Regarding the holding tank, the Applicant argued that this was their preferred choice because it would be far more affordable, would leave more of the lot in its natural state, and would be more suitable to the seasonal use of the building. He admitted that none of the conditions set out in Sentence 8.8.1.2.(1) concerning the acceptable installation of a Class 5 sewage system specifically pertain to his situation. Nevertheless, he indicated that the municipal council is willing to authorize the use of a holding tank for the subject lot if agreements are entered into with the local sewage hauler and the municipality regarding all aspects of the proposed Class 5 system. He submitted a letter supporting this assertion. The Applicant concluded by requesting that the Commission provide an exception to the criteria set out in Sentence 8.8.1.2.(1) of the OBC in order that he may install a holding tank.

6. Respondent's Position

The Respondent submitted that while he sympathized concerning the issue of the slope of the site, neither proposal offered by the Applicant met the appropriate standards in the OBC. T he Class 4 option faced considerable challenges due to the slope, he noted. The leaching bed fill with sides proposed as having a 1:3 slope, he argued, does not meet OBC Sentence 8.7.4.2.(8) and would not be stable. Moreover, as far as the holding tank was concerned, he indicated that it simply did not meet any of the allowable conditions for installation under the Code. For these reasons, the Respondent explained, he refused both of the Applicant's proposals.

7. Commission Ruling

It is the decision of the Building Code Commission that the proposed Class 4 filter bed and the proposed Class 5 holding tank intended to service a seasonal residential dwelling both fail to provide sufficiency of compliance with Sentence 8.7.4.2.(8) and Sentence 8.8.1.2. respectively.

8. Reasons

i) The slope in the vicinity of the filter bed is excessive.

ii) The Code is clear in prohibiting new development on a holding tank.

iii) There were no compensating measures proposed.

RULING

1. **The Applicant**

   Ms. Lillian Hall and Mr. Larry Hall, property owners, have applied for a building permit under the Building Code Act, 1992 to install Class 1 and 2 sewage systems at their proposed year-round dwelling at 24 Chalk Road, Scugog, Ontario.

2. **Description of Construction**

   The Applicants are proposing to install a new Class 1 and 2 sewage systems to serve a single detached Group C - residential dwelling. The proposed dwelling will contain two bedrooms, and will have a total finished area of 181.2 m^2.

   The proposed Class 1 system will consist of two composting toilets. The greywater generated by the 13.5 fixture units is to be disposed of in the proposed Class 2 leaching pit. The building is to be equipped with a pressurized water system.

The construction in dispute involves the calculated total daily design flow. The proposed building has an estimated daily design sewage flow of 2,700 litres per day, based on 13.5 fixture units at an assumed 200 L/day per unit with a pressurized water system. The Applicants, however, are proposing to install water conservation devices on as many of the fixture units as possible. The showers and faucets, for example, will be fitted with low flow heads. According to the Applicants' calculations this will reduce the daily sewage flow to roughly 450 L/day.

The Applicants had previously received a building permit for the construction of a Class 4 sewage system equipped with an Ecoflo tertiary treatment unit. This proposal was not pursued by the Applicants since installing this entire system, including the 15 by 7 m mantle, was considered to be destructive to the natural conditions of the site.

The lot is described as sloping (1:10) to the lake, mostly covered with mature trees (the lower third of the property is wetland) and measures approximately 67.8 by 35 m, for a total approximate area of 0.3 ha. The depth to the high groundwater table is roughly 1.1 m. The native soil has a percolation rate ranging between 15 to 30 minutes per centimetre. The site is located in the Oak Ridges Moraine and thus the soil is described as a mixture of sand and silt with bedrock found 80 m or more below the surface.

The water supply to the site will be by a drilled well.

3. **Dispute**

The issue at dispute between the Applicant and Respondent is whether the proposed Class 1 and 2 sewage systems to serve the subject permanent residential dwelling with an estimated daily design flow of 2,700 litres per day but which is equipped with certain water conservation devices provides sufficiency of compliance with Sentence 8.4.2.2.(1) of the Ontario Building Code. This Sentence requires that a greywater system, used in conjunction with a pressurized water system, that discharges into a Class 2 leaching pit be limited to a maximum capacity of 1,000 litres per day. The calculated flow far exceeds this amount. The Applicants have tried to achieve this limit by fitting many of their fixture units with water conservation devices.

4. **Provisions of the Ontario Building Code**

Sentence 8.4.2.2.(1) Maximum Sewage Flow

(1) A Class 2 sewage system shall not be constructed where the daily design greywater flow to the system exceeds 1,000 L/day.

5. **Applicant's Position**

The Applicants submitted that the proposed water conservation measures reduce their actual daily design flow to less than the calculated flow of 2,700 L/day. They indicated that they have proposed numerous devices to ration their water use. Besides low flow faucets and composting toilets they are also proposing to install a Miele dishwasher and a tumbler-type washing machine. The combined effect of all these devices would, they argued, reduce the daily flow to less than 450 L/day.

The Applicants described each fixture unit and indicated the potential water savings they would achieve. For example, since the composting toilets would not be connected to the proposed sewage system this would yield 100% savings. They explained that they derived these figures based on various sources, including the Light Grey Option report by CMHC which provided a break-down of water use per fixture units in a house. The Applicants also indicated that based on the OBC flow rates and estimated duration of use would mean that extremely high water consumption would have to occur (e.g. 55 loads of the dishwasher) to achieve anywhere near the volumes specified in the Code.

The Applicants argued that their derived figure of 450 L/day is a conservative estimate. They indicated that number was based on four people occupying the house when only two will use the residence on an on-going basis.

Lastly, they expressed a willingness to have their proposed system monitored.

6. **Respondent's Position**

The Respondent submitted that the calculated daily flow for the proposed dwelling with 13.5 fixture units is 2,700 L/day. Sentence 8.4.2.2.(1) of the Code, they noted, only allows 1,000 L/day for a leaching pit combined with a pressurized water system. As a result, they noted that the proposal did not conform to the requirements of the Code.

The Respondent also indicated that monitoring would be difficult due to lack of resources and a clear mandate.

7. **Commission Ruling**

It is the decision of the Building Code Commission that the Class 2 sewage system proposed to service a permanent residential dwelling fails to provide sufficiency of compliance with Sentence 8.4.2.2.(1) of the Ontario Building Code.

8. **Reasons**

The total fixture units which would drain to the Class 2 leaching pit would be 13.5. Based on 8.4.1.2.(2) the calculated flow for design purposes would be 2,700 litres per day, which exceeds the 1,000 litres per day permitted under Sentence 8.4.2.2.(1).

RULING

1. **The Applicant**

   Mr. David M. Welton, Assistant Secretary, Oakridge Heights Limited, has applied for a building permit under *the Building Code Act, 1992* to construct a high rise apartment building known as Oakridge Heights at 50 Old Mill Road, Oakville, Ontario.

2. **Description of Construction**

   The Applicant is proposing to construct a new ten storey (plus two levels of underground parking), Group C - residential apartment building. The structure will have a building area of 4,052.1 m^2. The building is to be of noncombustible construction and will be equipped with a sprinkler system, a fire alarm system and a standpipe and hose system.

   The construction in dispute involves the use of combustible polyvinyl chloride (PVC) window units in certain suites of the subject building, which is required to be noncombustible according to Article 3.2.2.42. of the OBC. These PVC window units have been installed in suite types A1 and A2 on level A, suite types B1 and B2 on level B, suite types 3 and 4 on floors Main to 7

inclusive, suite types 8 and 9 on floors 2 to 7 inclusive, suite types 5 and 6 on floors 8 and 9, and suite types 4 and 5 on floor 10. Specifically, the Applicant wishes to install the window units in the sunrooms/nooks of some suites as floor to ceiling window walls. As a result, the vertical separation of noncombustible material between suites of contiguous storeys will be approximately 250 mm. Further, the sunroom window walls, as an aggregate area of opening in the exterior wall face, will comprise 49.7% in suite types 2 and 3 and 70.7% in suite types 8 and 9.

To provide additional protection to prevent fire from spreading from suite to suite, the Applicant intends to cover the edge of the floor slab with an aluminium panel and will firestop it with a listed firestop system. The same firestopping will also be included at the demising walls between adjacent suites on the same storey.

The design and arrangement of the subject window units is similar to conventional units regarding their framing and glazing with insulated glass. The Applicant intends to install the subject window units because, in his view, they provide superior thermal, moisture and environmental performance and functionality.

3. **Dispute**

The issue at dispute between the Applicant and Respondent is whether the proposed combustible PVC window units, as a floor to ceiling window wall assembly with approximately only 250 mm of noncombustible vertical separation between storeys and constituting openings of roughly 50 to 70% aggregate area of the exterior wall face, provides sufficiency of compliance with Sentence 3.1.5.4.(5) of the Ontario Building Code. Clause (b) of this Sentence requires a separation of 1,000 mm of noncombustible material between windows in exterior walls in contiguous storeys. The proposed separation of noncombustible material between the PVC window units is roughly 250 mm. As well, Clause (c) of Sentence 3.1.5.4.(5) stipulates that only a total of 40% of an exterior wall face of a fire compartment can be used as window openings. In the Applicant's proposed sunrooms/nooks the aggregate area of window opening ranges from approximately 50 to 70%, depending on the suite.

4. **Provisions of the Ontario Building Code**

Sentence 3.1.5.4.(5) Combustible Glazing and Skylights

(5) Combustible window sashes and frames are permitted in a building required to be of noncombustible construction provided

(a) each window in a exterior wall face is an individual unit separated by noncombustible wall construction from every other opening in the wall,
(b) windows in exterior walls in contiguous storeys are separated by not less than 1000 mm (3 ft 3 in) of noncombustible construction, and (c) the aggregate area of openings in an exterior wall face of a fire compartment is not more than 40% of the area of the wall face.

5. **Applicant's Position**

The Applicant submitted that the subject windows provide sufficiency of compliance with Sentence 3.1.5.4.(5) for the following reasons.

Conventional aluminium thermally broken window systems are typically held together with a PVC or thermal vinyl break meaning that the integrity of such window units depend on the same combustible components as the subject windows. He noted that the frames of the proposed window walls are reinforced with formed steel sections inserted into the cavities of the PVC extrusions similar to aluminium window wall frames. Moreover, the use of PVC as the window frame material contributes very little combustible load to a suite when considering its contents, he asserted.

The Applicant also argued that the PVC frames will not adversely affect the flash-over time from one suite to another. As he noted, this is because fire containment in a suite depends on the integrity of the glazing. The glazing, he insisted, would break from radiant heat or thermal shock either prior to or at the time of flash-over. The failure of the glazing therefore would be the principal cause of flash-over from suite-to-suite. This would be the same for conventional aluminium frame windows with thermal breaks (which are not limited in terms of their vertical separation and aggregate opening area). The Applicant noted that the glazing in the subject window units provides standard thermal resistance. He also indicated that the additional firestopping provided vertically and horizontally between units would assist in the prevention of suite-to-suite flash-over.

The Applicant submitted several reports to support his arguments of sufficiency of compliance. He also submitted test results done at Underwriters' Laboratories of Canada in which the PVC window frames were tested for flame spread rating and smoke developed classification in accordance with CAN/ULC-S102.2, "Standard Method of Test for Surface Burning

Characteristics of Floor Coverings, and Miscellaneous Materials and Assemblies." The tests showed that the PVC material had a flame spread rating of between 55 and 65 and a smoke developed classification of between 425 and 475. The Applicant argued that these test results demonstrate that the PVC window frames posed no usually high risk in terms of their combustibility.

The Applicant indicated that the same window units are also proposed for two other high rise buildings (40 and 60 Old Mill Road) as part of the same complex.

6. **Respondent's Position**

The Respondent submitted that he supports the use of the PVC window units but he indicated that he feels it exceeds his jurisdiction under the OBC to allow these relaxations concerning the lack of the 1,000 mm vertical separation and the excess aggregate window opening area. He indicated that he had concerns regarding suite-to-suite spread of fire.

7. **Commission Ruling**

It is the decision of the Building Code Commission that the proposed combustible PVC window units installed in certain suites as a floor to ceiling wall assembly with approximately 250 mm of non-combustible vertical separation between storeys and constituting openings of approximately 50 to 70 percent of the aggregate area of the exterior wall face does not provide sufficiency of compliance with Sentence 3.1.5.4.(5) of the Ontario Building Code at Oakridge Heights, 50 Old Mill Road, Oakville, Ontario.

8. **Reasons**

i) The current reference, Sentence 3.1.5.4.(5) reads:

(a) each window in an exterior wall face is an individual unit separated by noncombustible wall construction from every other opening in the wall,
(b) windows in exterior walls in contiguous storeys are separated by not less than 1000 mm of noncombustible construction, and
(c) the aggregate area of openings in an exterior wall face of a fire compartment is not more than 40% of the area of the wall face.

ii) These minimum code requirements of 3.1.5.4.(5) have not been satisfied and no alternative compliance measures have been proposed.

RULING

1. **The Applicant**

   Mr. Clare Wamsteeker, Manager, Physical Plant, Brantwood Residential Development Centre, Brantford, Ontario, has received a building permit under the Building Code Act, 1992 and is currently constructing a group home known as the Paris Road Group Home, 100 Paris Road, Brantford, Ontario.

2. **Description of Construction**

   The Applicant is currently constructing a one storey (with a partial basement), group home with a building area of 312 m^2 (excluding carport) that is intended to house only 7 residents, who are supervised 24 hours a day by up to 3 or 4 full time staff members working on eight hour shifts. The building is of combustible construction and is classified as having a Group B, Division 3 (care) occupancy under the 1997 Ontario Building Code. The separations between the basement and ground floor and between the bedrooms within the group home will have a 3/4 hour fire-resistance rating.

   The structure will not be equipped with a fire alarm system, but will be supplied with a hard-wired interconnected smoke detection system and a sprinkler system. The Applicant is proposing that this latter system be designed and installed in accordance with the requirements of NFPA

13R, "Standard for the Installation of Sprinkler Systems in Residential Occupancies up to and Including Four Stories in Height."

3. **Dispute**

The issue at dispute between the Applicant and Respondent is whether a sprinkler system constructed to the NFPA 13R standard achieves sufficiency of compliance with Article 3.2.2.41. and Sentences 3.2.5.13.(1) and 3.2.5.13.(2) of the Ontario Building Code. Article 3.2.2.41. requires that a B3 occupancy must be sprinklered even though it may be of combustible construction. The dispute therefore centres on the type of sprinkler system that is required.

The NFPA 13R standard stipulates that a sprinkler system be designed and installed for all occupied rooms. The NFPA 13 standard, however, goes further by also requiring sprinklering in unoccupied areas such as closets and concealed spaces such as attics. Sentence 3.2.5.13.(1) states that a required sprinkler system must meet NFPA 13, whereas Sentence 3.2.5.13.(2), provides an exception to Sentence (1) by allowing low rise (four stories or less) residential occupancies to comply with the more relaxed sprinkler standards found in NFPA 13R.

If the subject B3 occupancy, as a low rise structure intended for a maximum of less than 10 people, could also be considered a residential occupancy according to the OBC, then the NFPA 13R standard would be an appropriate requirement for sprinklering.

4. **Provisions of the Ontario Building Code**

Article 3.2.2.41. Group B Division 2 or Division 3, One Storey, Sprinklered

(1) A building classified as Group B, Division 2 or Division 3 is permitted to be of combustible construction or noncombustible construction used singly or in combination, provided

(a) except as permitted by Sentence 3.2.2.7.(1), the building is sprinklered,
(b) it is not more than 1 storey in building height, and (c) it has a building area not more than 500 m^2 (5,380 ft^2). **Article 3.2.5.13. Automatic Sprinkler Systems**

(1) Except as permitted by Sentence (4), if Sentence (2) permits a single exit from a floor area classified as Group B or Group C occupancy, the exit shall be an exterior doorway not more than 1500 mm (4 ft 11 in) above adjacent ground level.

(2) Instead of the requirements of Sentence(1), NFPA 13R, "Standard for the Installation of Sprinkler Systems in Residential Occupancies up to and Including Four Stories in Height", is permitted to be used for the design, construction, installation and testing of an automatic sprinkler system installed in a building of residential occupancy that is not more than 4 storeys in building height.

5. **Applicant's Position**

At the outset the Applicant indicated that he had recently been to the Building Code Commission representing a project that was very similar to the one at hand, and since the dispute centred on the same issue he would be making similar arguments as before.

The Applicant submitted that the care occupancy currently under construction should be considered as residential facility under the OBC, thereby allowing the proposed NFPA 13R conforming sprinkler system to be installed. The Applicant argued that the subject group home physically resembles a house from both the exterior, with its small size, and interior, with its homelike floor plans. He noted that the construction techniques are also residential in nature. In his view, it was not the intent of the 1997 OBC to require the more onerous NFPA 13 sprinkler standard for such small buildings of residential character and function. He suggested that smaller facilities (as measured by their floor area or occupant load) in the B3 classification be allowed to comply with NFPA 13R.

Considering that all occupied rooms would be sprinklered (according to NFPA 13R), that fire separations would be provided between floors and bedrooms, that hard-wired interconnected smoke detectors would be installed, and that evacuation would be quick, the Applicant stated that the life safety of the residents would be adequately protected without relying upon the more rigorous NFPA 13 requirements.

Lastly, the Applicant indicated that many safety and accessibility features had been included in the subject home, with some of these being beyond the minimum standards required in the Code.

6. **Respondent's Position**

The Respondent chose not to attend the hearing. The Commission therefore relied upon his written submission.

The Respondent submitted that the subject care home is not a residential facility and thus the sprinkler system should be designed and installed according to NFPA 13. The building at hand, he argued, would contain more than two people who would require assistance to evacuate in an emergency. As a result, the subject building does not meet the criteria found in Article 3.1.2.5. of the 1997 Ontario Building Code that allows a care facility to be considered as having a residential occupancy. Therefore, in the Respondent's view, a care occupancy must conform with NFPA 13 standards for sprinkler design and installation.

7. **Commission Ruling**

It is the decision of the Building Code Commission that the proposed sprinkler system, designed according to NFPA 13R, provides sufficiency of compliance with Article 3.2.2.41. and Sentences 3.2.5.13.(1) and (2) of the Ontario Building Code at the Paris Road Group Home, 100 Paris Road, Brantford, Ontario provided a fire alarm system is installed throughout the building.

8. **Reasons**

i) Small residential type building;

ii) Less than 10 persons sleeping and occupying building;

iii) All safety features of B3 occupancy have been provided, other than NFPA 13; and,

iv) Fire separations consisting of 3/4 hour ratings between the basement and main floor and between bedrooms, corridors and living spaces have been provided.

RULING

1. **The Applicant**

   Mr. Clare Wamsteeker, Manager, Physical Plant, Brantwood Residential Development Centre, Brantford, Ontario, has received a building permit under the Building Code Act, 1992 and is currently constructing a group home known as the Paris Road Group Home, 100 Paris Road, Brantford, Ontario.

2. **Description of Construction**

   The Applicant is currently constructing a one storey (with a partial basement), group home with a building area of 312 m^2 (excluding carport) that is intended to house only 7 residents, who are supervised 24 hours a day by up to 3 or 4 full time staff members working on eight hour shifts. The building is of combustible construction and is classified as having a Group B, Division 3 (care) occupancy under the 1997 Ontario Building Code. The separations between the basement and ground floor and between the bedrooms within the group home will have a 3/4 hour fire-resistance rating.

   The structure will not be equipped with a fire alarm system, but will be supplied with a hard-wired interconnected smoke detection system and a sprinkler system. The Applicant is proposing that this latter system be designed and installed in accordance with the requirements of NFPA 13R, "Standard for the Installation of Sprinkler Systems in Residential Occupancies up to and Including Four Stories in Height."

3. **Dispute**

The issue at dispute between the Applicant and Respondent is whether a sprinkler system constructed to the NFPA 13R standard achieves sufficiency of compliance with Article 3.2.2.41. and Sentences 3.2.5.13.(1) and 3.2.5.13.(2) of the Ontario Building Code. Article 3.2.2.41. requires that a B3 occupancy must be sprinklered even though it may be of combustible construction. The dispute therefore centres on the type of sprinkler system that is required.

The NFPA 13R standard stipulates that a sprinkler system be designed and installed for all occupied rooms. The NFPA 13 standard, however, goes further by also requiring sprinklering in unoccupied areas such as closets and concealed spaces such as attics. Sentence 3.2.5.13.(1) states that a required sprinkler system must meet NFPA 13, whereas Sentence 3.2.5.13.(2), provides an exception to Sentence (1) by allowing low rise (four stories or less) residential occupancies to comply with the more relaxed sprinkler standards found in NFPA 13R.

If the subject B3 occupancy, as a low rise structure intended for a maximum of less than 10 people, could also be considered a residential occupancy according to the OBC, then the NFPA 13R standard would be an appropriate requirement for sprinklering.

4. **Provisions of the Ontario Building Code**

Article 3.2.2.41. Group B Division 2 or Division 3, One Storey, Sprinklered

(1) A building classified as Group B, Division 2 or Division 3 is permitted to be of combustible construction or noncombustible construction used singly or in combination, provided

(a) except as permitted by Sentence 3.2.2.7.(1), the building is sprinklered,
(b) it is not more than 1 storey in building height, and (c) it has a building area not more than 500 m^2 (5,380 ft^2). **Article 3.2.5.13. Automatic Sprinkler Systems**

(1) Except as permitted by Sentence (4), if Sentence (2) permits a single exit from a floor area classified as Group B or Group C occupancy, the exit shall be an exterior doorway not more than 1500 mm (4 ft 11 in) above adjacent ground level.

(2) Instead of the requirements of Sentence(1), NFPA 13R, "Standard for the Installation of Sprinkler Systems in Residential Occupancies up to and Including Four Stories in Height", is permitted to be used for the design, construction, installation and testing of an automatic sprinkler system installed in a building of residential occupancy that is not more than 4 storeys in building height.

5. **Applicant's Position**

At the outset the Applicant indicated that he had recently been to the Building Code Commission representing a project that was very similar to the one at hand, and since the dispute centred on the same issue he would be making similar arguments as before.

The Applicant submitted that the care occupancy currently under construction should be considered as residential facility under the OBC, thereby allowing the proposed NFPA 13R conforming sprinkler system to be installed. The Applicant argued that the subject group home physically resembles a house from both the exterior, with its small size, and interior, with its homelike floor plans. He noted that the construction techniques are also residential in nature. In his view, it was not the intent of the 1997 OBC to require the more onerous NFPA 13 sprinkler standard for such small buildings of residential character and function. He suggested that smaller facilities (as measured by their floor area or occupant load) in the B3 classification be allowed to comply with NFPA 13R.

Considering that all occupied rooms would be sprinklered (according to NFPA 13R), that fire separations would be provided between floors and bedrooms, that hard-wired interconnected smoke detectors would be installed, and that evacuation would be quick, the Applicant stated that the life safety of the residents would be adequately protected without relying upon the more rigorous NFPA 13 requirements.

Lastly, the Applicant indicated that many safety and accessibility features had been included in the subject home, with some of these being beyond the minimum standards required in the Code.

6. **Respondent's Position**

The Respondent chose not to attend the hearing. The Commission therefore relied upon his written submission.

The Respondent submitted that the subject care home is not a residential facility and thus the sprinkler system should be designed and installed according to NFPA 13. The building at hand, he argued, would contain more than two people who would require assistance to evacuate in an emergency. As a result, the subject building does not meet the criteria found in Article 3.1.2.5. of the 1997 Ontario Building Code that allows a care facility to be considered as having a residential occupancy. Therefore, in the Respondent's view, a care occupancy must conform with NFPA 13 standards for sprinkler design and installation.

7. **Commission Ruling**

It is the decision of the Building Code Commission that the proposed sprinkler system, designed according to NFPA 13R, provides sufficiency of compliance with Article 3.2.2.41. and Sentences 3.2.5.13.(1) and (2) of the Ontario Building Code at the Paris Road Group Home, 100 Paris Road, Brantford, Ontario provided a fire alarm system is installed throughout the building.

8. **Reasons**

i) Small residential type building;

ii) Less than 10 persons sleeping and occupying building;

iii) All safety features of B3 occupancy have been provided, other than NFPA 13; and,

iv) Fire separations consisting of 3/4 hour ratings between the basement and main floor and between bedrooms, corridors and living spaces have been provided.

RULING

1. **The Applicant**

   Mr. Martin Kimble, General Manager, Carriage Hills Resort 2 Corp., has received a building permit under *the Building Code Act, 1992* to construct two identical three storey residential (time-share) condominiums known as Phase II at the Carriage Hills Resort, Oro-Medonte Township, Ontario.

2. **Description of Construction**

   The Applicant is currently constructing two, three storey Group C - (residential) condominium buildings, each with a building area of 1,313.6 m2. Both buildings are to be constructed of combustible construction and will be equipped with a fire alarm system, but not a sprinkler system. Each building (known as buildings D and E) will house a total of 26 units, with the ground and second floors containing 10 units each and the third floors 6 units a piece. The six third storey units are located in the middle of the linear buildings, leaving both ends of the buildings at two storeys in building height. All condominium units are one storey.

The proposed buildings are the second phase of development of condominiums at the Carriage Hills Resort. The first phase consisted of buildings A, B and C which are two storeys in building height and contain a total of 52 units (16 in both buildings A and B and 20 in building C). This phase was constructed in 1997.

The construction in dispute involves the egress provisions from the two second storey units to be located at the extreme ends of both buildings where the structures are only two storeys in building height. (Of the 52 total units proposed therefore, the egress of only eight [four per building] are in dispute.) For all upper storey units in both buildings the main egress will be provided by means of exterior landings/corridors shared between two units and open exit stairs leading to grade level. As well, for the third storey units and the second floor units directly below them a secondary shared exit facility similar to that provided at the front of the building is to be provided at the rear of the units. However, the four pairs of second storey units located at the ends of both buildings are not provided with a secondary and independent egress route. Instead, they are only provided with a rear balcony.

3. **Dispute**

The issue at dispute between the Applicant and Respondent is whether the proposed fire alarm system, as an early warning device to be installed throughout the entire building, offered in lieu of a required second exit from the subject eight second storey units, provides sufficiency of compliance with Article 3.4.2.1. of the Ontario Building Code. This provision, with certain exceptions, requires that two exits are provided for every floor area intended for occupancy. The proposed structure does not qualify for any of the exceptions contained in Article 3.4.2.1.

4. **Provisions of the Ontario Building Code**

Article 3.4.2.1. Minimum Number of Exits

(1) Except as permitted by Sentences (2) to (4) and (6), every floor area intended for occupancy shall be served by at least 2 exits.

(2) A floor area in a building not more than 2 storeys in building height, is permitted to be served by one exit provided the total occupant load served by the exit is not more than 60, and

(a) in a floor area that is not sprinklered, the floor area and the travel distance are not more than the values in Table 3.4.2.1.A., or

(b) in a floor area that is sprinklered, (i) the travel distance is not more than 25 m (82 ft), and (ii) the floor area is not more than the value in Table 3.4.2.1.B.

(3) Except as permitted by Sentence (4), if Sentence (2) permits a single exit from a floor area classified as Group B or Group C occupancy, the exit shall be an exterior doorway not more than 1500 mm (4 ft 11 in) above adjacent ground level.

(4) A floor area containing only dwelling units having access to exit conforming to Sentences 3.3.4.4.(1) to (4) need not comply with Sentences (1) and (3).

(5) Exits are not required directly from rooftop enclosures that are provided with access to exits in conformance with Sentences 3.3.1.3.(5) and (6).

(6) Every room containing an assembly occupancy serving a hotel, and located in the building containing the hotel, shall be provided with not less than

(a) 3 separate egress doorways from the room where the occupant load is more than 600 persons, and
(b) 4 separate egress doorways from the room where the occupant load is more than 1000 persons.

(7) Each egress doorway in Sentence (6) shall be considered as contributing not more than

(a) one third of the required width where 3 egress doorways are required, and
(b) one fourth of the required width where 4 egress doorways are required.

5. **Applicant's Position**

The Applicant at the outset conceded that secondary, independent exits are required for the subject eight units. Further, he also supported the position of the Housing Development and Buildings Branch that, in general, a passive life safety system such as an exit is preferable to an active system such as a fire alarm. Nevertheless, he indicated that it was not his intention to dispute the requirements of Article 3.2.4.1., instead he argued that the proposed fire alarm system could be viewed as a compensating measure that achieves sufficiency of compliance with Article 3.4.2.1. To support this position, he noted that the first phase of the project was allowed to install a fire alarm system as a compensating measure for the lack of an additional and independent second storey exit. He added that a fire alarm system could be viewed as an alternative compliance measure similar to those found in Part 11 of the OBC.

6. **Respondent's Position**

The Respondent submitted that the proposed single exit second storey units do not comply with Article 3.4.2.1. of the Code. He argued that the principle of a second exit is a clear requirement found not only in this provision but throughout the OBC except under very limited circumstances. In his view, the proposed fire alarm system does not offer enough compensating safety to provide sufficiency of compliance with Article 3.4.2.1. As he noted, fire alarm systems do not address egress requirements and should not be seen as an appropriate mitigating measure. Safety systems that are passive, such as exits, are preferred to active systems such as fire alarms, he argued. This is because a passive system can be relied upon to perform its function in an emergency more so than an active system that may break down or fail.

Moreover, the Respondent rejected the Applicant's argument that the fire alarm system would be a compensating measure above the minimum required Code standards. In fact, he asserted that a fire alarm system would be necessary for the subject building according to the OBC Subsection 3.2.4. As a result, if required, the fire alarm system cannot be offered in lieu of another requirement.

Lastly, the Respondent also turned away the Applicant's proposal that the fire alarm system could be viewed as an alternative measure under Section 11.5. of the Code because, as new construction, none of Part 11 would apply to the subject building. As he pointed out, Part 11 only applies to renovation of existing buildings at least 5 years old.

7. **Commission Ruling**

It is the decision of the Building Code Commission that the proposed fire alarm system for the entire building, offered in lieu of a required second exit from certain second storey units, does not provide sufficiency of compliance with Article 3.4.2.1. of the Ontario Building Code at the Carriage Hills Resort Phase II, Township of Oro-Medonte, Ontario.

8. **Reasons**

i) Part 11 of the Code is not applicable since we are dealing with new construction;

ii) Two exits are required as per 3.4.2.1.; and,

iii) No compensating measures that were deemed to be adequate to provide sufficiency of compliance were offered.

Toronto, Ontario
The Applicant

Mr. Ray Hachigian
Inspector & Chief Building Official
Township of Archipelago
For the Respondent

RULING

1. **The Applicant**

   Mr. Barry Mills, President, 933891 Ontario Ltd., has received a building permit under *the Building Code Act, 1992* to construct a residence including second storey balconies on April 19, 1999 and an order to comply under *the Building Code Act (BCA), 1992* to provide the required minimum clearance distance between two balcony supporting piers and the distribution pipe in the newly constructed absorption bed at Flint Island B295 PCL 11706, former Township of Conger in the Township of the Archipelago, Ontario.

2. **Description of Construction**

   The property in question is a 4500 square foot Group C - residential occupancy constructed on a 17.2 acre parcel of land and serviced by a drilled well. The sewage system is a newly constructed Class 4 filter bed system consisting of two existing thirty four square metre beds with an additional bed to be added. The building under construction is described as a two storey, single detached structure.

The construction in dispute involves a lower (1st storey) deck and two supporting piers of an upper (2nd storey) balcony at the northeast corner of the building, which do not provide the minimum horizontal clearance distance of 5 m to distribution pipe in the filter bed as required by Sentence 8.2.1.6.(2) of the Ontario Building Code.

On September 21, 1998, the sewage permit was issued and on April 19, 1999 the Applicant was issued a building permit for the residence and an additional accessory sewage system. On May 6, 1999 an Order to Comply was issued requiring compliance with the clearance distance requirements referred to above. It was during an inspection of the proposed work that the clearance distance deficiencies were discovered.

3. **Dispute**

The issue at dispute between the Applicant and Respondent is whether the subject piers supporting the second storey balcony and the 1st storey deck as proposed, with as little as 2.13 m clearance distance from the distribution pipe in the filter bed, provides sufficiency of compliance with Sentence 8.2.1.6.(1) of the Ontario Building Code. This provision requires a minimum horizontal clearance distance of 5 m between a structure and a distribution pipe. With respect to the 1st floor deck, the Applicant committed to placing any additional deck piers a minimum of 2.13 m from the distribution pipe.

4. **Provisions of the Ontario Building Code**

Sentence 8.2.1.6.(2) Clearances for a Class 4 or 5 Sewage System

(2) Except as permitted by Article 3.1.8.17., the maximum area of glass block and wired glass panels not in a door, used in the locations shown in Table 3.1.8.15., shall conform to the Table.

5. **Applicant's Position**

The Applicant submitted that the proposed deck and second storey balcony will not interfere with the operation nor effectiveness of the septic system. He noted that the deck and balcony are sitting on bedrock and the base of the piers are a minimum 2 ft above the filter bed. Accordingly, given that the structures are supported on bedrock above the bed, they are unlikely to have an adverse impact on the operation or the effectiveness of the sewage system. Furthermore, given that the piers are two feet higher than the sewage system, the operation of the sewage system is unlikely to adversely impact on the structure.

The Applicant also argued that despite the proximity (less than half the required distance in the case of the deck: 13' as opposed to 1.5 m in the case of the balcony piers) the bed remains accessible for any repair or maintenance, and the structure can be maintained without affecting the filter bed.

Additionally the Applicant suggested that the existence of the 1st storey deck would keep people off the filter bed and assist in its' functioning.

6. **Respondent's Position**

The Respondent submitted that the subject deck and balcony do not meet the stipulated distance found in Sentence 8.2.1.6.(2). There is no definition of structure in the Regulation however the definition of "building" in Subsection 1.(1) of the Building Code Act (BCA), 1992 appears to reference the structural elements which are infringing on the required setback at issue.

Furthermore, the Respondent argued that because structure is not defined in the OBC, there is no direction to specifically exclude decks from this setback requirement or other exemptions that might render the stipulation not applicable.

The Respondent did not believe that there were issues relating to this situation other than the fact that he did not feel he had any discretion to vary the requirements in this part of the Code.

7. **Commission Ruling**

It is the decision of the Building Code Commission that the existing separation between the piers constructed to support the proposed second floor balconies and the distribution pipe in the existing filter bed, provide sufficiency of compliance with Sentence 8.2.1.6.(2) of the Ontario Building Code.

Further, it is the decision of the Building Code Commission that the proposed first storey raised walkway or deck (0.6 m above grade) supported on the existing piers and two proposed piers no closer than 2.13 metres to the distribution pipe, provide sufficiency of compliance with Sentence 8.7.1.6.(2) of the Ontario Building Code.

8. **Reasons**

i) The existing and proposed piers, constructed as sonotubes filled with concrete, are sufficiently separated from the distribution pipe to have no impact on the performance of the filter bed.

ii) The presence of the raised walkway at least 2.13 metres from the distribution pipe will have no impact on the performance of the filter bed.

iii) The disposal of sewage effluent into filter bed will have no impact on the performance of the piers.

RULING

1. **The Applicant**

   Mr. George Flumian, Chairman, Building Committee, Villa Marconi Long Term Care Centre, has applied for a building permit under the Building Code Act, 1992 to renovate an existing convent to create a care facility, known as the Villa Marconi Long Term Care Centre, at 1026 Baseline Road, Nepean, Ontario.

2. **Description of Construction**

   The Applicant has recently renovated a portion of an existing 1950s convent building and has changed its use to create a long term care centre with a capacity of 60 beds, 30 each on the second and third floors. The remaining existing portion of the structure (to the west) was previously converted to a community centre, the second floor of which is used as a chapel. The Applicant has also recently constructed an addition onto the east side of the proposed long term care facility to expand the available area for that use.

The structure is described as having two major occupancies; a Group B, Division 2 - (long term care facility) occupancy and a Group A, Division 2 - (community centre/chapel) occupancy. It is three storeys (the community centre is only two) in building height, plus a partial basement and has a total building area of 2,140 m^2, with the community centre being 645 m^2, while the nursing home facility (including new addition) measures 1,495 m^2. The building is considered to be of noncombustible construction and is equipped with a two-stage fire alarm system and is fully sprinklered throughout.

The construction in dispute involves the interior enclosure walls facing the building's central corridors of three exit stairs, two of which are located in the existing renovated portion of the structure, whereas the third is located in the new addition. Specifically, in the case of the existing stair enclosures, the original plain glass and wood frame glazing were replaced with wired glass in pressed steel frames having a one hour fire-resistance rating. The original paired narrow leaf doors were also replaced with single, wider (1,042 mm), hollow metal, 45 minute rated doors equipped with panic hardware. Both the wired glass and steel doors are labelled to indicate their fire-resistance rating.

The design intent of the new enclosure assembly was to match that of the existing original enclosure, especially in terms of the total amount of glazing and its overall configuration. As such, the new enclosures consist almost entirely of glass with each composed of 11 (roughly 40 cm by 95 cm) panes arranged horizontally in five rows containing two panes each, with the topmost row of three panes extending over the door. In the new exit found in the addition, the enclosure was designed in a near exact way, with the exception that the door is slightly wider.

During the partial demolition of the existing building's interior prior to the recent construction, however, the entire enclosure walls were removed.

For all three exits at which this issue has arisen the disputed enclosure assembly occurs on every floor. All of the stairs are required exits which lead directly to the exterior at grade. As a temporary measure, until a decision by the Building Code Commission has been rendered, the Applicant has covered the glazed area of each enclosure with drywall. None of the other wall and floor/ceiling assemblies in the existing and new stairs are in dispute.

3. **Dispute**

The issue at dispute between the Applicant and Respondent is whether the glazed area of the recently constructed exit stair enclosures, designed to match the existing original assembly but

with a greater degree of fire-resistance rating, provides sufficiency of compliance with Article 3.1.8.16. of the Ontario Building Code. Sentence (1) of this provision restricts the aggregate of glazed area in a door to 0.8 m^2, while Sentence (2) limits the aggregate of glazed area not in a door also to 0.8 m^2. The area of wired glass in the Applicant's as built enclosures far exceed the 0.8 m^2 total allowed in Sentence 3.1.8.16.(2).

As much of the subject structure is an existing building that underwent a renovation, Part 11 of the Building Code therefore applied. Since the original intent was to retain much of the interior as possible and nearly all the exterior, the project was originally considered a basic renovation. As well, an analysis of the change of use of the structure found that the Hazard Index at 6 matched the Construction Index of 6. Based on the first proposal, under Compliance Alternative B14, the original enclosure assemblies could have remained in place.

Subsequent demolition, however, removed much of the interior of the building, including the original stair enclosures, and thus went beyond what is considered basic renovation. Apparently at this point there was some confusion or lack of communication between Applicant and Respondent regarding these changes in the building and the corresponding regulatory requirements. The Applicant's plan then was, as discussed, to match and replace the previous non-rated enclosures in terms of glazed area with new 1 hour-rated enclosures. The dispute was only realized by the parties after construction was well under way.

4. **Provisions of the Ontario Building Code**

Article 3.1.8.16. Area Limits for Wired Glass and Glass Block

(1) Except as permitted by Article 3.1.8.17., the maximum area of wired glass in a door used in the locations shown in Table 3.1.8.15. shall conform to the Table. (See Appendix A.)

(2) Except as permitted by Article 3.1.8.17., the maximum area of glass block and wired glass panels not in a door, used in the locations shown in Table 3.1.8.15., shall conform to the Table.

5. **Applicant's Position**

The Applicant acknowledged at the outset that the total glazed area in the subject stair enclosures do not comply with Article 3.1.8.16. of the Code. She submitted, however, that the as constructed situation is "a substantial improvement" over the previous condition which, she added, could have been retained or matched etc. under Part 11 if the renovation had not been so

extensive. As a result, the Applicant indicated that her approach would be to demonstrate sufficiency of compliance with OBC 3.1.8.16. and to argue that the new performance level is better than the previous situation.

In terms of sufficiency of compliance the Applicant argued that the new materials are superior to the original construction, which the Code would have allowed. In fact, she noted that the entire enclosure assembly provides a one hour separation which is much more than the previous non-rated combustible assembly. Further, she also noted that the additional demolition that triggered this issue was done, in part, as a voluntary and pro-active measure to install sprinklering throughout the building. Without the sprinklers and the associated demolition the new wall assembly would have been able to match existing construction. The sprinklering, she noted, enhanced the safety of the building greatly beyond what is required. The sprinklers, acting to suppress a fire, would be especially useful by the enclosures since they would minimize the chance of fire spreading by radiation and thereby keeping the temperature rise in check.

The Applicant also argued that the exit stairs will not be exposed to a high fuel load in the immediate vicinity of the enclosures elements. If smoke does contaminate a stairwell there are two other exits serving the residents' floors, she noted. Moreover, the residents' floor areas are subdivided into three compartments separated by a 1 hour rating each served by an exit stair.

Lastly, the Applicant argued that the extensive glazing has additional health and safety benefits in a nursing home facility. The glazing, for example, enhances visual supervision of persons using the stairs, which is important considering the age of the residents. The extra glazing would be especially useful if a person required assistance in the stairwell. In terms of the overall health of the residents, she noted that the additional glazing would allow more natural light into the corridors, which would be quite beneficial in an institutional environment.

6. **Respondent's Position**

The Respondent submitted that references or arguments regarding the relevance of Part 11 to the subject enclosures were nullified when approximately 90 percent of the interior of the building was demolished, including the enclosures which were replaced by the new wall assemblies. At this point, as he indicated, Article 3.1.8.16. was the only germane criteria and the current as constructed enclosures far exceed the permitted aggregate glazed area. He noted that there are no construction difficulties etc. that would prevent the Applicant from meeting Article 3.1.8.16.

While the Respondent recognizes that the new assemblies provide a greater degree of fire separation than the original situation, he does not view this upgrade as an equivalent under Section 2.7 of the OBC. As he noted, there are no tests established to verify this upgrade, nor is there any history of past performance. Further, he indicated that the Code does not specifically allow sprinklering as a compensating measure for this type of modification to a required exit.

Finally, the Respondent argued that, considering many of the residents will be non-ambulatory and will need assistance, the integrity of the exits from a fire compartmentalization aspect is crucial. In an emergency, staff and fire fighters will need extra time to assist many of the occupants of the building down the exit stairs. For this basic reason they have concerns about the extent of glazing in the enclosures.

7. **Commission Ruling**

It is the decision of the Building Code Commission that the upgraded noncombustible one hour rated pressed steel frame with wired glass panels and one hour rate hollow metal door proposed to match the existing stairwell enclosure does not provide sufficiency of compliance with Article 3.1.8.16. at the Long Term Care Centre, 1026 Baseline Road, Nepean, Ontario.

8. **Reasons**

i) The Applicant was unable to demonstrate to the Building Code Commission that the existing measures provide sufficiency of compliance.

APPEARANCES

Mr. J. M. O. Grey
Toronto Dominion Bank
Toronto, Ontario
The Applicant

Mr. Brad Swainsbury
Building Inspector
City of Burlington
For the Respondent

RULING

1. **The Applicant**

   Mr. J. M. O. Grey, Vice-President and Chief Architect, Toronto Dominion Bank, has received a building permit under *the Building Code Act, 1992* to construct a Toronto Dominion retail bank branch at the Millcroft Shopping Centre, 2000 Appleby Line, Building G, Unit G1, Burlington, Ontario.

2. **Description of Construction**

   The Applicant has recently constructed a 371.7 m^2, Group E - (retail bank branch outlet) mercantile occupancy for the Toronto Dominion Bank. The bank branch is located within a larger retail plaza that is described as one storey in building height, 2044.6 m2 in building area, and contains Group D and Group E occupancies. The plaza is noncombustible construction and is equipped with a sprinkler system, but is not provided with a fire alarm system.

The construction in dispute involves whether the 2,896 mm by 2,134 mm vault is required to be sprinklered. The Applicants have not currently provided a sprinkler head in the vault interior. The vault, manufactured by Chubb Security Ltd., consists of wall, floor and roof concrete modular panels a minimum of 190 mm thick with a four hour fire resistance rating. The vault is equipped with a smoke detector and a heat detector that are connected to the bank's security system. This system is monitored 24 hours a day.

3. **Dispute**

The issue at dispute between the Applicant and Respondent is whether the bank vault interior, as constructed, without sprinkler protection in a building required to be sprinklered, provides sufficiency of compliance with Sentence 3.2.5.13.(1) of the Ontario Building Code. This provision requires that where a building is to be sprinklered the system must be designed, constructed, installed and tested in conformance with NFPA 13, "Standard for the Installation of Sprinkler Systems". The NFPA 13 standard, specifically Subsection 1-6.1, requires that all areas of a building be sprinklered, including rooms and spaces, except where expressly omitted. Bank vaults, however, are not included as one of the exceptions listed in the NFPA 13 standard.

4. **Provisions of the Ontario Building Code**

Article 3.2.5.13.(1) Automatic Sprinkler Systems

(1) Except as permitted by Sentences (2), (3) and (4), an automatic sprinkler system shall be designed, constructed, installed and tested in conformance with NFPA 13, "Standard for the Installation of Sprinkler Systems". (See Appendix A.)

5. **Applicant's Position**

The Applicant acknowledged that NFPA 13, as cited in OBC Sentence 3.2.5.13.(1), does require that bank vaults be sprinklered. However, he indicated that it was his intention to argue that the subject unsprinklered vault does provide sufficiency of compliance with OBC 3.2.5.13.(1).

The Applicant noted that, in his view, this issue arose because the NFPA, an American standard, had changed over the last ten to fifteen years with respect to the requirement for sprinkler protection in bank vaults. Canadian building regulations such as the OBC, meanwhile continue to reference the NFPA 13 standard. That the OBC references the NFPA 13 standard is not the

issue, what is, he argued, is that NFPA did not consult with or notify any Canadian financial institutions before making this revision.

Regarding the sufficiency of the unsprinklered vault, the Applicant then argued that the chance of a fire occurring in a vault is very unlikely. Their records which date back to 1962 do not indicate any such occurrence. Moreover, since the vault is built according to Subsection 3.1.5. of the OBC (Noncombustible Construction) and because it is a nearly air tight space, any fire would have little oxygen to fuel itself with. If, on the other hand, a fire were to start outside the vault elsewhere in the building the risk of damage to the contents within the vault is low due to its four hour fire-resistance rating. There have been a few such incidences and in all cases, even when the surrounding building was a total loss, very little damage to the contents occurred. As the Applicant noted, the bank has had a far greater history of loss due to water damage than from fire.

The vaults are also equipped with two early warning devices; a smoke detector, and a heat detector. These devices, connected to the bank's alarm system, will provide adequate notice to the fire department to respond to a fire on the premises, he argued. The Applicant is also proposing to install a sprinkler head outside and above the actual vault itself. He indicated that he is also willing to enhance the suppression system immediately outside the vault door and to change the interior cabinets to ones constructed of metal. The Applicant added that the carpet in the bank is fire retardant.

The Applicant then compared bank vault regulations and construction to that of electrical vaults, which he noted are listed as an excepted space under NFPA 13. He noted that electrical vaults, while also required to be noncombustible and be equipped with smoke detection, are generally built to a lesser standard in terms of thickness of concrete and fire-resistance rating. Further, electrical vaults are also not required to provide heat detection. He argued that bank vaults, being built to a higher standard, should also be exempt from sprinklering.

For these reasons, the Applicant concluded that the as-built unsprinklered vault provides sufficiency of compliance with Sentence 3.2.5.13.(1).

6. **Respondent's Position**

The Respondent submitted that OBC Sentence 3.2.5.13.(1) requires as per NFPA 13 that all spaces in a building required to be sprinklered must be equipped with a sprinkler head. NFPA 13 clearly does not allow this exception.

Regarding the Applicant's arguments concerning sufficiency of compliance the Respondent noted that the vault is loaded with combustible materials and is open during day time operations which in event of fire would allow oxygen to fuel flames. As well, the early detection systems installed in the vault do not provide any suppression to actively fight the fire. The Respondent also argued that the construction and use of the vault does not make it comparable to an electrical vault, therefore the same exemption should not apply. There are numerous penetrations in the subject vault which could possibly allow any fire to spread.

The Respondent indicated that sprinkler technology has advanced to the point that accidental set off rarely occurs. A chemical sprinkler system, for example, could be designed to suit the banks purposes.

For these reasons, the Respondent indicated that he felt that he did not have the authority to allow the disputed construction.

7. **Commission Ruling**

It is the decision of the Building Code Commission that the bank vault interior is required to be installed with sprinkler protection in accordance with Sentence 3.2.5.13.(1) of the Ontario Building Code at the Toronto Dominion Bank, Millcroft Shopping Centre, 2000 Appleby Line, Building G, Unit G1, Burlington, Ontario.

8. **Reasons**

i) Where a building is required to be sprinklered, Sentence 3.2.5.13.(1) of the Ontario Building Code requires that an automatic sprinkler system must be designed, constructed, installed and tested in conformance with NFPA-13-1994 "Standard for the Installation of Sprinkler Systems".

ii) Subsection 1-6.1 of the NFPA-13 states that "a building, where protected by an automatic sprinkler system installation, shall be provided with sprinklers in all areas". The intent of the Standard is to require sprinklers in all rooms and spaces, except where specific sections of NFPA-13 permit the omission of sprinklers. However, bank vaults are not one of the given exceptions.

iii) No sufficiency of compliance was demonstrated by the Applicant that were considered sufficient by the Building Code Commission.

RULING

1. **The Applicant**

   Mr. Joe Amorim, J.M.C. Amorim Foods Inc., has received a building permit under *the Building Code Act, 1992* to construct a new Swiss Chalet restaurant at 1220 Brant Street, Burlington, Ontario.

2. **Description of Construction**

   The Applicant has recently constructed a single storey, 553.5 m^2 (in building area), Group A, Division 2 occupancy to be used as a 232 seat restaurant. The building is of combustible construction and is equipped with a fire alarm system.

   The construction in dispute involves a raised platform located in the centre of the dining area. There are eight booths (four with four seats and four with two seats each) on the subject raised dining platform containing a total of 24 seats. Half of the booths face to the outside of the platform while the other half face a 1,092 mm wide passageway running across the width of the platform's interior.

The platform measures 3.33 m by 3.86 m for a total area of 12.85 m^2. It is raised by the height of one step, specifically 170 mm. Directly under the oak nosing of the raised platform is a 10 mm in diameter lighting string. At each end of the platform's access passageway 237 mm long handrails are provided. The handrails are fastened to the low perimeter wall of the platform that forms the backing of the end booths. The lowest portion of the handrails are mounted 900 mm from the top of the platform and are set at a 45 degree angle from a horizontal plane.

For the patrons using the 12 seats in the four booths facing the outside of the platform it is necessary to step up onto the platform and slide along the bench-type seat. There is no handrail provided to assist them in getting in and out and up and down the 170 mm height of the platform. While the patrons seated in the interior booths have handrails to assist them in ascending and descending the platform, the handrails do not extend 300 mm at the top and bottom of the step.

3. **Dispute**

The issue at dispute between the Applicant and Respondent is whether the as built raised dining platform complies with Sentences 3.3.2.13.(1) and 3.4.6.4.(7) of the Ontario Building Code. Sentence 3.3.2.13.(1) permits such raised platforms as long as it meets certain requirements, including illumination and handrails on each side. The applicant's handrails, however, do not meet all the requirements for handrails that are located in a stair. Sentence 3.4.6.4.(7), for example, stipulates that a 300 mm extension of the handrail is necessary at the top and bottom of the stair. Such an extension is not proposed. Further, the exterior booths are not provided with any handrails.

4. **Provisions of the Ontario Building Code**

Sentence 3.3.2.13.(1) Risers for Stairs

(1) In a Group A, Division 2 occupancy used for the serving of food and beverages, an interior flight of stairs with fewer than 3 risers is permitted provided it

(a) is not less than 900 mm (2 ft 11 in) wide,
(b) is illuminated at all times that occupants are on the premises, and
(c) has a handrail on each side.

Sentence 3.4.6.4.(7) Handrails

(7) At least one handrail at the side of a stairway or ramp shall extend horizontally not less than 300 mm (11 3/4 in) beyond the top and bottom of the stairway or ramp. (See A-3.4.6.4.(5) in Appendix A.)

5. **Applicant's Position**

The Applicant submitted that the subject platforms are commonly employed as part of the interior design of a restaurant. He indicated that, in his view, the raised dining platform is an architectural element and does not meet the definition of a stair in the OBC. In fact, he argued it should be considered as furniture. As a result, he argued that the disputed provisions of the Code are not relevant since they pertain to stairs or ramps.

Nevertheless, the Applicant did indicate that many of the safety concerns regarding the riser for the interior booths were being addressed. For example, the booth passageway at 1,092 mm in width comfortably exceeds the required 900 mm. The booth is also well lit at all times and has additional lighting on the riser itself. Moreover, a handrail has been provided on both sides of the two "exits" from the platform. The flooring finishes are different between platform and the lower floor making the change in elevation easier to see. Therefore, even if the platform was considered a stair under the OBC it would meet most of the requirements of Sentence 3.3.2.13.(1), the Applicant argued. He indicated that they are also willing to extend the handrail somewhat at the top and bottom of the platform riser by wrapping it around the exterior booth wall, thereby lengthening the handrail and making it more useful and safer. A full 300 mm extension, however, would be a dangerous obstacle in the passageway.

As far as the issue of the exterior booths, the Applicant argued that they should not be considered as a stair. Patrons do not actually step up the riser, in fact they slide into the booth. In doing so they usually use the table and/or the back of the seat as an object to steady themselves. As such, he stated that the requirements of Sentences 3.3.2.13.(1) and 3.4.6.4.(7) were not applicable. Further, the Applicant argued that it was impractical to include some of the required measures in this application.

6. **Respondent's Position**

The Respondent submitted that the subject dining platform should be considered as having a single stair riser. Consequently, the provisions of the OBC relating to stairs apply.

Regarding the step leading to the interior booths, the Respondent acknowledged that the Code, specifically Article 3.3.2.13., allows a single riser stair within a restaurant, but he argued that the handrails must therefore conform to Sentence 3.4.6.4.(7) and be provided with a 300 mm extension at the top and bottom of the stairs. He noted that the Applicant's proposed handrail extension does not meet this requirement. The extension is important, he argued, because it allows the public the opportunity to steady themselves before and after negotiating the stair.

On the issue of the exterior booths, the Respondent indicated that he considers the single riser at this location also a stair. He argued that Sentence 3.4.6.3.(5) of the Code requires every stair to have a landing at the top and bottom. The exterior booth arrangement has no landing area at the top of the stair, he noted.

7. **Commission Ruling**

It is the decision of the Building Code Commission that the proposed raised dining platform does not fall under the definition of a stair and therefore extensions are not required for the handrail and the raised dining platform need not be required to conform with Sentence 3.3.2.13.(1) of the Ontario Building Code at the Swiss Chalet Restaurant, 1220 Brant Street, Burlington, Ontario.

It is also the decision of the Building Code Commission that the exterior booths do not require handrails nor need to conform to OBC 3.3.2.13. at the Swiss Chalet Restaurant, 1220 Brant Street, Burlington, Ontario.

8. **Reasons**

i) Drawing A-102 dated July 6, 1999 and February 15, 1999 indicate that illumination and handrails provide sufficiency of compliance.

ii) The platform is an integral part of the booth and therefore may be considered as a single piece of furniture.

iii) The single step in the exterior booths does not provide access to any other booth or floor areas in the restaurant.

RULING

1. **The Applicant**

   Ms. Nancy E. Clark and Mr. David A. Clark, property owners, have applied for a building permit under *the Building Code Act, 1992* to install a new, partially raised Class 4 sewage system as a replacement for their existing failed system at 2249 Country Road 11, Selby, Ontario.

2. **Description of Construction**

   The Applicants are proposing to install a new, partially raised Class 4 sewage system as a replacement for their existing failed system at their residence. The building is classified as having a Group C- (single detached dwelling unit) residential occupancy and is described as having 210 m^2 of total finished area, 17.5 fixture units, three bedrooms and a total daily design flow of 1,700 L/d. No work is proposed for the dwelling itself.

   The existing system is approximately forty to fifty years old and is composed of a 3,375 litre tank (750 gallons) septic tank connected to an unknown length and area of clay distribution pipe set in the native soil. The tank itself has been perforated and is currently being used as a

makeshift holding facility, which requires a pump out every seven or eight days. The clay pipe leading from the tank to the bed was no longer functional. Regarding the distribution tiles, which is fed (or should fed) by gravity disposal, no information was provided.

The proposed new replacement sewage system is described as a partially raised Class 4 system with a sand filter bed. It consists of a 4,500 litre septic tank which transmits effluent by gravity to a nearby pump chamber, both of which will be located near the dwelling at the south end of the property. From there the effluent is to be pumped roughly 20 m to the distribution pipe, which is higher in elevation and located at the north end of the site.

The proposed filter bed will be partially raised by 0.3 m due to the high watertable found at 1.4 m below grade. The bed is to contain four runs of 76 mm diameter distribution pipe each 9.15 m in length for a total of 36.6 m. The pipes will be placed at 0.75 m on centre and all runs are to be connected with perpendicular pipe at both ends. The pipes are to be set in a 0.3 m thick layer of crushed stone ranging from 53 to 18 mm in size. The stone layer, measuring 3 by 10 m, will be separated from the raised covering material above by geotextile fabric or building paper. Below the stone layer will be a 0.75 m thick sand filter media composed of imported materials with an approximate T-time of 8 minutes per centimetre. The contact area of the sand filter bed will also be 30 m^2 (3 by 10 m). The total depth of the entire filter bed will be 1.15 m below the existing grade.

The site measures approximately 22 m by 40 m, has a total area of roughly 880 m^2 and is described as a "hamlet lot". It has a seven percent downward slope in a north to south direction. The native soil has a percolation rate in the range of 2.5 to 4 minutes per centimetre. The site is served by a dug well. The neighbouring property immediately to the east is served by a similarly constructed well which is situated roughly only 5 m away from the common lot line.

The issue regarding the failed sewage system and the decision to replace it arose after the Applicants recently bought the subject property. Upon occupancy they immediately discovered that the sewage system was not functioning. After inspection by the local health unit it was determined that the system had not worked for some time, and further, that their well was contaminated. While the well is generally down gradient of the leaching bed, it has not been conclusively determined through, for example, a dye test analysis that there is a causal link between the two. Nevertheless, they decided that the entire system urgently needed to be replaced.

The construction in dispute involves the proposed location of the new raised filter bed and its proximity to the two dug wells, approximately 26 and 21.5 m away on the Applicants' and neighbour's properties respectively. The location of the existing, failed tile field is not precisely known, however, it is most accurately described as being in the centre of the subject property, and despite the fact that the proposed filter bed location would be an improvement over the current situation, i.e., it would be farther away from the wells, due to the constricted lot size, the bed cannot be constructed at the distance required for new system installations. While it is known that the Applicants' well is contaminated (they have been drinking bottled water since they discovered the problem), the water quality of the neighbour's well has not been determined since he is not interested in having it tested.

3. **Dispute**

The issue at dispute between the Applicant and Respondent is whether the new Class 4 sewage system, specifically the sand filter bed, proposed as a replacement for the existing failed system is required to comply with Sentence 8.2.1.6.(2), or may be permitted to comply with Sentence 11.5.1.1.(1) as it refers to Table 11.5.1.1.C. and Compliance Alternative C84.1 of the Ontario Building Code. Sentence 8.2.1.6.(2) of the OBC sets out the requirements for, among other things, the minimum clearance distances between distribution piping (Table 8.2.1.6.B.) and dug wells such as the two in dispute. Table 8.2.1.6.B. stipulates that 30 m is the required distance in this instance. Germane to the subject dispute is the fact that Part 8, as with most other parts of the Code, deals with the standards for new construction.

Sentence 11.5.1.1.(1), on the other hand, states that a compliance alternative may be substituted for the new construction standards found in various parts of the Code, including Part 8, if the Chief Building Official is satisfied that, as is possible in this case, there is a "construction difficulty". The compliance alternative relevant to this dispute is C84.1, which allows the existing clearances to be maintained if the proposed sewage system is the same class as the existing system and if the replacement system does not exceed the capacity of the old system. Sentence 11.5.1.1.(1), as is the case with all of Part 11, deals with construction undertaken on an existing building or sewage system and is intended to provide reasonable standards considering that much of the intended overall construction for the site is already in place.

The Applicants' proposed sand filter bed, although farther away than the existing leaching bed, will still be only 26 m from their well and 21.5 m from the neighbour's well. They applied for a permit for their replacement system on the basis that this lack of clearance distance constitutes a

"construction difficulty" as per Sentence 11.5.1.1.(1). Their application was turned down by the Health Unit because they lacked the adequate setbacks to the subject wells. Neither party raised nor disputed the requirements of Article 8.9.1.2. which prohibits effluent impact on ground water and wells.

4. **Provisions of the Ontario Building Code**

Sentence 8.2.1.6.(2) Clearances for a Class 4 or 5 Sewage System

(2) Except as provided in Sentences 8.2.1.4.(1) and (2), a distribution pipe shall not be located closer than the minimum horizontal distances set out in Table 8.2.1.6.B. and these distances shall be increased when required by Sentence 8.7.4.2.(9).

Sentence 11.5.1.1.(1) Compliance Alternatives

(1) A compliance alternative shown in Tables 11.5.1.1.A., 11.5.1.1.B., 11.5.1.1.C., 11.5.1.1.D/E. or 11.5.1.1.F. may be substituted for a requirement contained in Part 3, 4, 5, 6, 7 or 8 where the chief building official is satisfied that compliance with the requirement is impracticable because,

(a) of structural or construction difficulties, or
(b) it is detrimental to the preservation of a heritage building.

5. **Applicant's Position**

The Applicants submitted that their proposed Class 4 sewage system, as a replacement system, should be allowed to utilize the existing setbacks to the wells under Part 11. They noted that Sentence 11.5.1.1.(1), specifically compliance alternative C84.1, states that existing clearances are acceptable where a sewage system is replaced with another system in the same class and the capacity (as in daily design sewage flow) of the replacement system is also the same.

The Applicants argued that they comply with both of these conditions. In fact, their replacement system will improve the performance level over the current one. Moreover, since no work is proposed for the building, the capacity of the new system will be the same. (They noted the recently approved Ontario Regulation 278/99 clarifies that the "capacity" of a sewage system is determined by calculating the daily design sewage flow.) As a result, the Applicants stated that, in their view, due to their construction difficulty related to setbacks on their property, the Respondent should have authorized the use of compliance alternative C84.1, as per Sentence 11.5.1.1.(1).

The Applicants noted that there are numerous ways that their proposed system will be a major improvement over their existing sewage system. To start with, they are proposing to install a larger septic tank equipped with an effluent filter in the outlet baffle. Together these improvements will be better able to begin the process of separation and allow for greater bacterial action. They are also proposing to construct a sand filter media bed where none existed prior. As well, most importantly, they intend to locate the filter bed farther from the wells than the existing leaching bed.

The Applicants admitted that the quality of the well water was an issue. However, they rejected the Respondent's argument that their own consultant warned them that all affected wells be abandoned. The only well of which work was contemplated and discussed with their consultant was their well, and replacing it with a cased well 6 m deep or more was considered only as an additional safety measure. They stressed that their consultant never indicated to them, as it seemed the Respondent was alleging, that their proposed replacement system would not be possible due to the lack of available clearance distance. In fact, they argued that his advice was exactly the opposite - that their proposal should be allowed under Part 11.

The Applicants also recognized that the impact of the replacement system would be felt by their neighbours as well. Nevertheless, they indicated that their neighbours concurred with their plans and agreed that their proposal would improve the current situation. To this end, they produced letters of support from both of their neighbours immediately adjacent to their property.

Lastly, the Applicants commented that Part 11, in their view, was intended precisely for people in circumstances as they now found themselves. They noted that Eastern Ontario especially has many smaller rural or village/hamlet lots that are serviced by old, ineffective sewage systems. Without recourse to Part 11, they argued, many of these lots could be rendered useless. They expressed hope that the Building Code Commission would consider this in their deliberations. Finally, they reiterated their view that their proposal should be accepted with reduced setbacks under Part 11.

6. **Respondent's Position**

The Respondent submitted that he considers the Applicants' proposal to be a new sewage system installation. Accordingly, he indicated that all minimum clearance distances, including those to the subject wells, must be complied with. He based this view on Article 11.1.1.2. which classifies a sewage system as a building system, and on Article 11.3.1.2. which, as he argued, requires a new building system to comply with "all other Parts of the Code", including Part 8.

To support his view that the proposed system should be considered new, the Respondent described the aspects of the system that are new or different than the existing one. He noted, for example, that the septic tank will be larger and that it is to be equipped with an effluent filter. The pump, necessary to transmit effluent to the raised bed, is also a new feature of this system. As well, the bed itself is completely different - it will be raised and will be composed of new materials imported to the site as the filter media. Even all the distribution pipe is new in the Applicants' proposal. Thus, since none of the current system is being reused, relocated or extended the proposal cannot be considered a basic renovation, the Respondent argued. Further, although technically within the same class system many upgrades and modifications have been proposed, therefore he asserted that this must be viewed as an entirely new system.

The Respondent rejected the idea that compliance alternative C84.1 should be used in this case. The quality of not only the Applicants' well water but also that of their neighbour's was his chief concern and the main reason the application was refused. It is precisely for reasons such as this in an existing situation, he argued, that Sentence 11.5.1.1.(1) allows compliance alternatives to be used only when "the chief building official is satisfied that compliance with the requirement (in this case Table 8.2.1.6.B.) is impractical..." Moreover, the Respondent stated that he does not believe that a lack of clearances constitutes a construction difficulty as intended in OBC 11.5.1.1.(1). Even if he was to allow the Applicants' their requested relaxation which may pollute their well, he indicated that he viewed it as his duty to protect the neighbour's well. In fact, he argued that Part 11 should not be available in circumstances where contamination of another property is a likely hazard.

The Respondent also argued that even if the Commission were to approve the subject proposal based on part 11, other provisions in the Code specifically do not allow contamination of a well. While he acknowledged these provisions (Article 8.9.1.2.) regulate on-going operational concerns and therefore may not apply to the subject dispute, he indicated that when, or if, the proposed sewage system is constructed and if contamination is linked to the system he would possibly rely upon such powers in the future. To avoid this situation, the Respondent indicated that he would be satisfied with the present proposal if a tertiary treatment unit were added or a cased well greater than 6 m deep was built (as the consultant recommended). This, he noted, would protect both wells and would resolve the situation now.

Lastly, the Respondent conceded that the proposal is "a significant improvement over the existing system and it is in the best interests of all parties to install a new system." Nevertheless, without the minimum clearance distances he believes the potential risk of contaminating the

wells is too high. He does not believe the mandate or intent of the OBC or the Building Code Act is to knowingly allow this.

7. **Commission Ruling**

It is the decision of the Building Code Commission that the compliance alternative shown in Table 11.5.1.1.C. (C84.1) may be substituted for the requirement contained in Article 8.2.1.4. with respect to the proposed replacement filter bed.

8. **Reasons**

i) There is an existing septic system which could be repaired under the Code.

ii) The distribution pipes in the proposed filter bed are no closer to the existing dug well on the subject property and adjacent lots than the existing distribution pipe to the existing leaching bed.

iii) The proposed performance level of the proposed sewage system exceeds the performance level of the existing system if it were operating properly.

RULING

1. **The Applicant**

   Ms. Debra Ann Alexander, owner, has applied for a building permit under

   the Building Code Act, 1992

   to install a new, partially raised, Class 4 sewage system at 731 Alexander Drive, Peterborough, Ontario.

2. **Description of Construction**

   The Applicant is proposing to construct a new partially raised, Class 4 sewage system to serve a renovated single, detached Group C - residential (seasonal) dwelling located on Lake Chemong. The new sewage system is necessary due to the Applicant's intention to renovate the existing cottage residence by constructing a two storey addition, including garage, and by remodelling the existing structure. The new building will be used year round. The proposed addition is to sit

directly over the current location of the leaching bed. The renovated dwelling will contain 4 bedrooms, 24 fixture units and will increase the total finished floor area to approximately 219 m^2 from the existing 84.2 m^2. The total daily design sewage flow rate will be 2,200 l/d.

The Applicant has offered two proposals regarding possible locations of the filter bed sewage system. Option one, their preferred choice, would be to locate the new sewage system between the building and the road (referred to here as the "roadside" location). Option two would be to locate the system between the building and the lake ("lakeside"). For both locations the basic design elements of the proposed sewage system are the same. The new sewage system would consist of a 4,500 L septic tank connected to a partially raised leaching bed containing distribution pipe. Existing soils will be used in either system. The percolation time ranges from 2 to 8 min/cm.

Regarding the roadside location, due to the presence of the high groundwater table found at approximately 1.3 m below grade, the proposed bed will be raised by 0.3 m. The filter bed at this location would be long and narrow with two 19 m runs of distribution pipe (38 m total) placed at 1 m on centre. At the lakeside location a higher groundwater table, at roughly 0.6 m below grade, requires that the proposed bed be raised to a least 0.9 m. At this location the Applicant is proposing to configure the bed with 5 runs of 5.5 m each (27.5 m total) spaced apart 1 m on centre.

The site is described as covered with grass, slightly sloping towards the lake and measures 30.5 m by 43.6 m. The subject dwelling is served by a well water system. The drilled well is located on the front (lakeside) of the property.

The construction in dispute concerns the clearance distances involved in both locations. For the proposed roadside location the required setbacks, because of the raised bed, have been increased to 3.6 m from the lot line and 5.6 m from the building. The renovated building, however, is to be situated approximately 8.8 m from the rear lot line. The Applicant's proposed roadside location would therefore only provide a separation of 2.8 m to the lot line and 5 m to the cottage. Another issue is that the weeping tile around the existing and proposed building is to run directly to the lake.

For the lakeside location the raised bed has increased the setbacks to 16.8 m from the lake as well as 6.8 m from the building. The front of the proposed renovated building will be separated from the lake by 26 m. At this site, the proposed location of the sewage system at 17 m from the

lake would comply with that requirement but would only offer a separation of 5 m to the building. Further, only 17 m would separate the distribution pipe from the existing well.

Also in dispute is the proposed filter loading rate for the roadside location. Considering the size of the proposed leaching bed, at roughly 21 m^2, and considering the daily design flow of 2,200 l/d, the loading rate would exceed 75 L/m^2/day. The basal loading rate would also be excessive. The loading rate for the lakeside proposal is not in dispute.

3. **Dispute**

The issue at dispute between the Applicant and Respondent is whether the raised Class 4 sewage system proposed with reduced clearance distances in either location and an undersized leaching bed area provides sufficiency of compliance with Sentences 8.7.4.2.(9) and 8.7.5.2.(3) respectively of the Ontario Building Code. The first provision requires that the minimum clearance distances permitted in Table 8.2.1.6.B of the Code be increased by twice the height that the leaching bed is raised above the original grade. The effect of this requirement is that in both the Applicant's proposed locations not all setbacks can be met. The latter provision requires that the loading rate at the top of the leaching bed cannot exceed 75 L/m^2/ day. With a daily flow of 2,200 l/d an area of at least 30 m^2 is needed to meet the loading requirement. The Applicant's roadside location does not meet this.

4. **Provisions of the Ontario Building Code**

Sentence 8.7.4.2.(9) Construction Requirements

(9) The distances as set out in Column 2 of Table 8.2.1.6.B. shall be increased by twice the height that the leaching bed is raised above the original grade.

Sentence 8.7.5.2.(3) Loading Requirements

(3) Where the total daily design sanitary sewage flow does not exceed 3000 L, the effective area shall be such that the loading on the surface of the filter medium does not exceed 75 L/m^2 per day.

5. **Applicant's Position**

The Applicant indicated that his preferred location for the sewage system was to the rear of the cottage, near the roadside. This is because from an environmental point of view he felt it was

safer to put the system farther from the Lake. Another problem with the lakeside location is that the well would have to be moved to another location.

The Applicant submitted that his proposed roadside location, while not meeting all required setbacks, meets the intent of the Code, specifically Sentence 8.7.4.2.(9). He argued that because the proposed system would encroach mostly on a road (which is bounded by an open field on the other side) the impact would be minimal. He then submitted letters from property owners on either side and the owner of the road indicating support for the road side location.

The Applicant also acknowledged that the roadside location did not meet the loading requirements. He indicated, however, that their actual use of the building would be less than the estimated 2,200 l/d of daily design flow.

The Applicant, during the hearing, then offered to install a tertiary treatment unit to pretreat the effluent prior to distribution, as a compensating measure for the minor deficiency regarding the setbacks to the road. A shallow buried trench leaching bed was also proposed as the method of disposal.

6. **Respondent's Position**

The Respondent submitted that his refusal was based on insufficient area and a lack of adequate clearance distances provided. As a result he did not view the proposed system as providing sufficiency of compliance with the subject provisions of the OBC. He did indicate, however, that he would be comfortable with the proposed tertiary treatment unit as a compensating measure.

7. **Commission Ruling**

It is the decision of the Building Code Commission that the proposed compensating measure of the installation of a tertiary treatment system with denitrification and a shallow buried trench provides sufficiency of compliance with respect to the minor shortfall in setback required to the property line.

8. **Reasons**

i) There are no land uses on the privately owned road fronting on the property line which will be impacted be the shortfall in setback.

ii) The owner of the road has provided a letter accepting the encroachment on the setback.

iii) The tertiary treatment system will provide improved effluent quality reducing the potential impacts of the effluent disposal.

RULING

1. **The Applicant**

   Mr. Andre Beaudet, homeowner, has received an order to comply under *the Building Code Act (BCA), 1992* to provide the required minimum clearance distance between a deck attached to the rear of his residence and the septic tank and he has also applied for a building permit under the BCA to enclose the subject deck with a screened porch at 128 Greystone Drive, Carp, Ontario.

2. **Description of Construction**

   The Applicant's Group C - residential dwelling is currently served by a raised Class 4 sewage system. The building is described as a two storey, single detached structure containing 3 bedrooms, 23.5 fixture units and has a total finished floor area of 234.6 m^2. The calculated total daily design flow is 2,200. Both the building and the sewage system were built in 1991.

   The existing sewage system consists of a 4,500 L septic tank which feeds, by gravity disposal, a leaching bed composed of six runs of 8 m each (spaced 0.75 m apart on centre) for a total of 48

m of distribution pipe. The partially raised disposal bed and surrounding mantle has a total hydraulic footprint of 127.8 m^2 and was constructed with 25 mm crushed stone as the filter media set in and covered with sand fill. The sewage system appears to be functioning well.

The site is a 0.8 hectare "country lot". The soil profile is sand to a depth of 0.9 m and the high water table is located at least 0.9 m below grade. The site is served by a well water system.

The construction in dispute involves an "L-shaped" deck (6.7 m by 3.66 m) connected to the rear of the dwelling. The deck does not provide a minimum of 1.5 m clearance distance to the septic tank servicing the property. The actual distance between the edge of the deck and the septic tank is 0.45 m. (The deck was apparently built sometime after the house and septic system were constructed. There is disagreement between the parties as to whether the deck had been constructed at the time of the final inspection and when the final inspection occurred - either early 1992 or March 93.) The rectangular septic tank measures approximately 2.9 m by 1.65 m, with the width of the tank running parallel to the deck.

In the fall of 1998, the Applicant submitted a building permit application to enclose the deck with an unconditioned screened porch. This proposal is also in dispute. As part of the proposed work the existing deck foundation piers would be replaced with 6 x 6 pressure treated posts to support the weight of the enclosure. It was during an inspection for the proposed work that the clearance distance deficiency was discovered. The application for the porch enclosure was subsequently denied and an Order to Comply was issued regarding the noncompliance with the spatial separation.

3. **Dispute**

The issue at dispute between the Applicant and Respondent is whether the deck, as constructed, with less than 1.5 m clearance distance from the existing septic tank, provides sufficiency of compliance with Sentence 8.2.1.6.(1) of the Ontario Building Code. This provision requires a minimum horizontal clearance distance of 1.5 m between a structure and a treatment unit, such as a septic tank. The Applicant's existing deck, which he is proposing to enclose, is currently situated only 0.45 m from the septic tank.

4. **Provisions of the Ontario Building Code**

Article 8.2.1.6. Clearances for a Class 4 or 5 Sewage System

(1) Except as provided in Sentences 8.2.1.4.(1) and (2), a treatment unit shall not be located closer than the minimum horizontal distances as set out in Table 8.2.1.6.A.

(2) Except as provided in Sentences 8.2.1.4.(1) and (2), a distribution pipe shall not be located closer than the minimum horizontal distances set out in Table 8.2.1.6.B. and these distances shall be increased when required by Sentence 8.7.4.2.(9).

(3) No building shall be constructed closer to any part of a sewage system than the clearances listed in Articles 8.2.1.5. or 8.2.1.6.

5. **Applicant's Position**

The Applicant submitted that the deck as it is currently constructed does not interfere with the operation nor effectiveness of the septic system. He noted that since the development of the property eight years ago, the septic tank has needed servicing only once. Consequently, he argued that the existing configuration meets the intent of Sentence 8.2.1.6.(1) of the OBC regarding clearance distances.

The Applicant noted that when these sewage system were regulated by the Ministry of Environment under the Environmental Protection Act the Ministry circulated a directive dated June 14, 1999 stating that a person should not construct nor renovate a building in relation to a sewage system if it is "likely to affect the operation or effectiveness of the sewage system." He further noted that the letter goes on to indicate that "(c)learly,... a deck, provided that it does not cover the sewage system, will not affect the sewage system." Since the current setback requirements found in the OBC are the same as those under the Environmental Protection Act, he argued that the intent behind the provisions is similar. Therefore, because his deck does not cover the septic tank the Applicant indicated, in his view, that the existing setback of 0.45 m meets the intent of Sentence 8.2.1.6.(1).

The Applicant also argued that despite the proximity of the deck, the tank is still accessible. He argued that there is enough space on his two acre property that the tank could easily be removed and/or serviced without any interference with the deck or the leaching bed. He indicated that he had consulted an area sewage system contractor who assured him that removing the tank would not be a problem.

Lastly, the Applicant stated that he inherited this problem in February of 1992 when they purchased their house. He indicated that the house and deck have not been altered in any way since then.

6. **Respondent's Position**

The Respondent submitted that with only a 0.45 m separation, the subject deck does not meet the stipulated distance found in Sentence 8.2.1.6.(1). The actual clearance distance is less than one third of the required setback, he noted. A deck, the Respondent argued, should appropriately be viewed as a structure under Part 8 of the Code. The foundation for a deck raises similar construction issues as other, larger structures. Moreover, the same replacement and maintenance concerns would be present. He indicated that a quick sampling of other jurisdictions in North America found that 1.5 m seemed to be the minimum clearance to a treatment unit.

Further, the Respondent argued that because structure is not defined in the OBC there is no direction to specifically exclude decks from this setback requirement. He also noted that there are no exemptions that would be applicable to this situation since it should not be considered a renovation under Part 11, nor do the soil conditions warrant it.

As the Respondent noted, the deck was built without a building permit. Had a permit been applied for, it would have been refused. This would have true even under the previous regulations in the Environmental Protection Act. As well, without benefit of design review and inspection, he indicated that he had concerns about the structural adequacy of the existing deck.

Finally, the Respondent indicated that he had serious doubts about whether replacement of the current septic tank would be possible without significant disruption to the deck foundation. In his view, a 1.5 m excavation pit around the perimeter of tank would be necessary. Lastly, he expressed concern about the proposed new foundation piers and the possibility that they may undermine the soil under the tank and the leader pipe from the house.

7. **Commission Ruling**

It is the decision of the Building Code Commission that the separation between the existing septic tank and the existing deck provides sufficiency of compliance with Table 8.2.1.6.A.

With respect to the proposal to construct a screened porch on top of the existing deck and to modify the existing support piers, it is the decision of the Building Code Commission that the

separation between the modified structure and the existing septic system provides sufficiency of compliance with Table 8.2.1.6.A. as long as the design of the support piers is confirmed by a consulting engineer and the engineer certifies that the construction did not negatively affect the performance of the septic tank.

8. **Reasons**

i) The deck and tank have been in co-existence from some six plus years and the presence of the deck has not apparently impacted on the performance of the septic tank.

ii) The septic tank is adequately separated from the foundation of the existing dwelling.

iii) The existing deck and proposed structure will not negatively impact on the maintenance of the tank.

iv) There is sufficient area and accessibility to replace the septic tank 1.5 metres beyond the structure.

v) The engineering certification ensures that the performance of the tank will not be negatively impacted by the construction.

RULING

1. **The Applicant**

   Mr. D. Hudgins, Construction Manager, Liza Homes, Richmond Hill, Ontario, has applied for a building permit under *the Building Code Act, 1992* to construct a temporary sales pavilion at 1180 Harmony Road North, Oshawa, Ontario.

2. **Description of Construction**

   The Applicant is proposing to construct a two storey, 161 m^2 (1,733 ft^2) temporary sales pavilion to serve as a model home and office space in which new houses of a residential subdivision will be featured and promoted and where sales will be negotiated. The ground floor of the proposed building will be open to the public for the above uses. It will consist of 145 m^2 (1,560 ft^2) of reception, display and office areas, with a 16 m^2 (172 ft^2) veranda. The second floor will be accessible to employees only and will contain 29.7 m^2 (320 ft^2) of office space and a 8.4 m^2 (90 ft^2) viewing terrace. The building is classified as having a Group D- business (office) occupancy.

3. **Dispute**

The issue at dispute between the Applicant and Respondent is whether the proposed structural integrity of the ground level floor assembly of the subject temporary sales pavilion built to accommodate a live load of 2.4 kPa complies with Article 4.1.6.2. of the Ontario Building Code. This Article provides the appropriate criteria for determining live loads used in the calculation of structural support for occupancies that are not specifically set out in Article 4.1.6.3. Temporary sales pavilions of this nature are not listed in Table 4.1.6.3., and therefore based on the criteria of Article 4.1.6.2. the Applicant is proposing to use 2.4 kPa as the design live load. Article 4.1.6.3., however, does include live load specifications for general office areas. The live load prescribed in Table 4.1.6.3. for the ground floor of an office area is 4.8 kPa.

4. **Provisions of the Ontario Building Code**

Article 4.1.6.2. Uses Not Stipulated

(1) Where the use of an area of floor or roof is not provided for in Article 4.1.6.3., the specified live loads due to the use and occupancy of the area shall be determined from an analysis of the loads resulting from

(a) the weight of the probable assembly of persons,
(b) the weight of the probable accumulation of equipment and furnishings, and
(c) the weight of the probable storage of materials.

5. **Applicant's Position**

The Applicant submitted that by employing a design live load of 2.4 kPa the resulting structural integrity of the ground floor would be more than adequate for the proposed weight of people, furniture and material and would therefore satisfy the requirements of Article 4.1.6.2.

The Applicant argued that classifying the building as an office occupancy is onerous. In his view, the sales pavilion is a specialty use not specifically covered by the Code. He noted that the structure will not be designed nor used in a crowded or cluttered fashion. In fact, in order to achieve a spacious look to demonstrate and emphasize the full sizes of the model rooms, the ground floor will not have an abundance of furniture and materials. As far as the total occupant load, the Applicant argued that it would be relatively low. He indicated that at the most only two

people work on the ground floor at any one time and that personal appointments are set up with prospective buyers. There may also be occasional drop-in customers.

Nevertheless, the Applicant proposed to use a design live load based that employs certain cautious assumptions. For example, based on the total building area, and assuming an occupant load of roughly one person per 2.8 m^2 (30 ft^2) the total ground floor occupant load would be 58 persons. He argued that this occupant load, assuming an average weight of 90.7 kg (200 lbs), would only result in a uniform live load of 0.3 kPa (6.7 psf). Doubling this load to account for any impact factor and doubling it again to account for the furniture would only yield a uniform load of 1.2 kPa (27 psf). As a result, with a design live load of 2.4 kPa (50 psf) an additional safety factor of 86% will be built into the proposed floor assembly to handle any non-uniform loads. This design, he asserted, will be more than sufficient to ensure that the safety of the public is adequately addressed.

Lastly, the Applicant noted that the Respondent supported his position.

6. **Respondent's Position**

The Respondent submitted that since the proposed temporary sales pavilion is classified as a Group D - business (office) occupancy. Article 4.1.6.3. and specifically Table 4.1.6.3. of the OBC are the applicable provisions and not Article 4.1.6.2. As a result, he argued that the proposed live load of 2.4 kPa (50 psf) for the ground floor of the sales office does not comply with the required 4.8 kPa (100 psf) as per Article 4.1.6.3. The Respondent then added that while the Code, in his view, stipulates a 4.8 kPa (100 psf) load, he indicated that for the proposed use, 2.4 kPa (50 psf) should be more than adequate.

7. **Commission Ruling**

It is the decision of the Building Code Commission that the structural support system of the first floor of the temporary sales pavilion designed to accommodate a live load of 2.4 kPa (50 psf) does not comply with Article 4.1.6.2. of the Ontario Building Code at the Liza Homes Sales Office, 1180 Harmony Road North, Oshawa, Ontario.

8. **Reasons**

i) Application does not provide sufficiency of compliance with Subsection 4.1.6. of the Building Code.

ii) The design load for office areas, as stated in Table 4.1.6.3., has been in effect in the Ontario Building Code since 1975.

RULING

1. **The Applicant**

   Mr. Richard Biffis, Vice President Construction, The Kaitlin Group, Scarborough, Ontario, has applied for a building permit under the *Building Code Act, 1992*, to construct a residential subdivision known as the Port of Newcastle development, Clarington, Ontario.

2. **Description of Construction**

   The Applicant is proposing to construct a residential subdivision known as the Port of Newcastle. The individual houses are classified as having a Group C occupancy and are described as two storey with a total floor area of 206 m^2 (2,217 ft^2).

   The construction in dispute involves the drainage below the concrete floor slabs at the basement level. The Applicant is not proposing to install drain pipes (connected to the perimeter weeping tile) under the slabs-on-ground. Instead, the proposed slabs would rest on polyethylene damproofing membranes on top of compacted granular material. A weeping tile drainage system for the foundation wall will be provided at the level of the footing.

3. **Dispute**

The issue at dispute between the Applicant and Respondent is whether the basement slab-on-ground floors constructed without a drainage system below complies with Article 9.16.3.1. of the Ontario Building Code. This provision requires that unless it can be demonstrated as unnecessary drainage or grading shall be used to prevent the ingress of water underneath a floor-on-ground.

4. **Provisions of the Ontario Building Code**

Subsection 9.16.3. - Drainage

9.16.3.1. - Control of Water Ingress

(1) Except as provided in Article 9.16.3.2. or where it can be shown to be unnecessary, ingress of water underneath a floor-on-ground shall be prevented by grading or drainage.

9.16.3.2. - Hydrostatic Pressure

(1) Where groundwater levels may cause hydrostatic pressure beneath a floor-on-ground, the floor-on-ground shall be:

(a) a cast in place concrete slab; and
(b) designed to resist such pressures.

5. **Applicant's Position**

The Applicant submitted that his proposal to construct the proposed slabs-on-ground without a drainage system below complies with Article 9.16.3.1. because such a system, in his view, is only required when ground water problems are anticipated as determined by a soils report or a site inspection. He argued that the need to install a sub-slab drainage system occurs when a water problem has been detected in the soil. He indicated that the Respondent has this reversed, believing that the drainage system is an automatic requirement until the soil is found to be problem free. This, the Applicant argued, places an unnecessarily heavy burden of proof

regarding the soil on the proponent and probably results in many unneeded drainage systems being installed in areas where the soil conditions do not require it

In his view, the intent of the Code is to prevent ingress of water under a slab-on-ground by using a drainage system where necessary. There was no indication of groundwater problems in his soils report or as noted by any site inspection. He argued that the engineering report should be viewed as reliable evidence of the site's condition. He added that the condition of each property would be verified and they would make any necessary adjustments, e.g. providing a sub-slab drainage system if needed, during construction.

With no identifiable groundwater issue, the Applicant concluded by arguing that it made little sense therefore to install a sub-slab drainage system for each property.

6. **Respondent's Position**

The Respondent submitted that a drainage system below the slab-on-ground is required as per Article 9.16.3.1. and thus the proposal does not meet Code. He noted that to date the municipality has not been able to conclusively determine whether the soil conditions would require (or not) that a sub-slab drainage system is necessary. Based on this uncertainty about the soil and considering that OBC 9.16.3.1. states that drainage is required "except... where it can be shown to be unnecessary..." (which he indicated has not been proven), the Respondent argued that his interpretation of this Code provision dictates that in the subject circumstance a sub-slab drainage system is required. As he noted, Article 9.16.3.1., in his view, is drafted in such a way as to require a drainage system until it can be proven unnecessary.

Having made the case for the requirement of the drainage system, the Respondent then argued however that he felt this was an example of an excessive requirement found in the Building Code that goes beyond the minimum standards designed to ensure the intended levels of health, life safety, and property protection and barrier-free accessibility. He indicated that he viewed the sub-slab drainage standards as requirements that enhance comfort and quality of construction but are not minimum housing standards.

Nevertheless, he indicated that they have been enforcing the Code as written because that is their responsibility as a municipal building department.

7. **Commission Ruling**

It is the decision of the Building Code Commission that drainage below a slab-on-ground at the Port of Newcastle development in Clarington may be eliminated provided an engineer reports to the Chief Building Official that drainage is unnecessary, or where groundwater levels may cause hydrostatic pressure beneath a floor-on-ground, the floor-on-ground shall be a cast in place concrete slab and designed to resist such pressures.

8. **Reasons**

(i) Article 9.16.3.1. states "Except as provided in Article 9.16.3.2. or where it can be shown to be unnecessary, egress of water underneath a floor-on-ground shall be provided by grading or drainage".

RULING

1. **The Applicant**

   Mr. D. Hudgins, Construction Manager, Liza Homes, Richmond Hill, Ontario, has applied for a building permit under *the Building Code Act, 1992* to construct a temporary sales pavilion at 1180 Harmony Road North, Oshawa, Ontario.

2. **Description of Construction**

   The Applicant is proposing to construct a two storey, 161 m^2 (1,733 ft^2) temporary sales pavilion to serve as a model home and office space in which new houses of a residential subdivision will be featured and promoted and where sales will be negotiated. The ground floor of the proposed building will be open to the public for the above uses. It will consist of 145 m^2 (1,560 ft^2) of reception, display and office areas, with a 16 m^2 (172 ft^2) veranda. The second floor will be accessible to employees only and will contain 29.7 m^2 (320 ft^2) of office space and a 8.4 m^2 (90 ft^2) viewing terrace. The building is classified as having a Group D- business (office) occupancy.

3. **Dispute**

The issue at dispute between the Applicant and Respondent is whether the proposed structural integrity of the ground level floor assembly of the subject temporary sales pavilion built to accommodate a live load of 2.4 kPa complies with Article 4.1.6.2. of the Ontario Building Code. This Article provides the appropriate criteria for determining live loads used in the calculation of structural support for occupancies that are not specifically set out in Article 4.1.6.3. Temporary sales pavilions of this nature are not listed in Table 4.1.6.3., and therefore based on the criteria of Article 4.1.6.2. the Applicant is proposing to use 2.4 kPa as the design live load. Article 4.1.6.3., however, does include live load specifications for general office areas. The live load prescribed in Table 4.1.6.3. for the ground floor of an office area is 4.8 kPa.

4. **Provisions of the Ontario Building Code**

Article 4.1.6.2. Uses Not Stipulated

(1) Where the use of an area of floor or roof is not provided for in Article 4.1.6.3., the specified live loads due to the use and occupancy of the area shall be determined from an analysis of the loads resulting from

(a) the weight of the probable assembly of persons,
(b) the weight of the probable accumulation of equipment and furnishings, and
(c) the weight of the probable storage of materials.

5. **Applicant's Position**

The Applicant submitted that by employing a design live load of 2.4 kPa the resulting structural integrity of the ground floor would be more than adequate for the proposed weight of people, furniture and material and would therefore satisfy the requirements of Article 4.1.6.2.

The Applicant argued that classifying the building as an office occupancy is onerous. In his view, the sales pavilion is a specialty use not specifically covered by the Code. He noted that the structure will not be designed nor used in a crowded or cluttered fashion. In fact, in order to achieve a spacious look to demonstrate and emphasize the full sizes of the model rooms, the ground floor will not have an abundance of furniture and materials. As far as the total occupant load, the Applicant argued that it would be relatively low. He indicated that at the most only two

people work on the ground floor at any one time and that personal appointments are set up with prospective buyers. There may also be occasional drop-in customers.

Nevertheless, the Applicant proposed to use a design live load based that employs certain cautious assumptions. For example, based on the total building area, and assuming an occupant load of roughly one person per 2.8 m^2 (30 ft^2) the total ground floor occupant load would be 58 persons. He argued that this occupant load, assuming an average weight of 90.7 kg (200 lbs), would only result in a uniform live load of 0.3 kPa (6.7 psf). Doubling this load to account for any impact factor and doubling it again to account for the furniture would only yield a uniform load of 1.2 kPa (27 psf). As a result, with a design live load of 2.4 kPa (50 psf) an additional safety factor of 86% will be built into the proposed floor assembly to handle any non-uniform loads. This design, he asserted, will be more than sufficient to ensure that the safety of the public is adequately addressed.

Lastly, the Applicant noted that the Respondent supported his position.

6. **Respondent's Position**

The Respondent submitted that since the proposed temporary sales pavilion is classified as a Group D - business (office) occupancy. Article 4.1.6.3. and specifically Table 4.1.6.3. of the OBC are the applicable provisions and not Article 4.1.6.2. As a result, he argued that the proposed live load of 2.4 kPa (50 psf) for the ground floor of the sales office does not comply with the required 4.8 kPa (100 psf) as per Article 4.1.6.3. The Respondent then added that while the Code, in his view, stipulates a 4.8 kPa (100 psf) load, he indicated that for the proposed use, 2.4 kPa (50 psf) should be more than adequate.

7. **Commission Ruling**

It is the decision of the Building Code Commission that the structural support system of the first floor of the temporary sales pavilion designed to accommodate a live load of 2.4 kPa (50 psf) does not comply with Article 4.1.6.2. of the Ontario Building Code at the Liza Homes Sales Office, 1180 Harmony Road North, Oshawa, Ontario.

8. **Reasons**

i) Application does not provide sufficiency of compliance with Subsection 4.1.6. of the Building Code.

ii) The design load for office areas, as stated in Table 4.1.6.3., has been in effect in the Ontario Building Code since 1975.

RULING

1. **The Applicant**

   Mr. Richard Biffis, Vice President Construction, The Kaitlin Group, Scarborough, Ontario, has applied for a building permit under the *Building Code Act, 1992*, to construct a residential subdivision known as the Port of Newcastle development, Clarington, Ontario.

2. **Description of Construction**

   The Applicant is proposing to construct a residential subdivision known as the Port of Newcastle. The individual houses are classified as having a Group C occupancy and are described as two storey with a total floor area of 206 m^2 (2,217 ft^2).

   The construction in dispute involves the drainage below the concrete floor slabs at the basement level. The Applicant is not proposing to install drain pipes (connected to the perimeter weeping tile) under the slabs-on-ground. Instead, the proposed slabs would rest on polyethylene damproofing membranes on top of compacted granular material. A weeping tile drainage system for the foundation wall will be provided at the level of the footing.

3. **Dispute**

The issue at dispute between the Applicant and Respondent is whether the basement slab-on-ground floors constructed without a drainage system below complies with Article 9.16.3.1. of the Ontario Building Code. This provision requires that unless it can be demonstrated as unnecessary drainage or grading shall be used to prevent the ingress of water underneath a floor-on-ground.

4. **Provisions of the Ontario Building Code**

Subsection 9.16.3. - Drainage

9.16.3.1. - Control of Water Ingress

(1) Except as provided in Article 9.16.3.2. or where it can be shown to be unnecessary, ingress of water underneath a floor-on-ground shall be prevented by grading or drainage.

9.16.3.2. - Hydrostatic Pressure

(1) Where groundwater levels may cause hydrostatic pressure beneath a floor-on-ground, the floor-on-ground shall be:

(a) a cast in place concrete slab; and
(b) designed to resist such pressures.

5. **Applicant's Position**

The Applicant submitted that his proposal to construct the proposed slabs-on-ground without a drainage system below complies with Article 9.16.3.1. because such a system, in his view, is only required when ground water problems are anticipated as determined by a soils report or a site inspection. He argued that the need to install a sub-slab drainage system occurs when a water problem has been detected in the soil. He indicated that the Respondent has this reversed, believing that the drainage system is an automatic requirement until the soil is found to be problem free. This, the Applicant argued, places an unnecessarily heavy burden of proof

regarding the soil on the proponent and probably results in many unneeded drainage systems being installed in areas where the soil conditions do not require it

In his view, the intent of the Code is to prevent ingress of water under a slab-on-ground by using a drainage system where necessary. There was no indication of groundwater problems in his soils report or as noted by any site inspection. He argued that the engineering report should be viewed as reliable evidence of the site's condition. He added that the condition of each property would be verified and they would make any necessary adjustments, e.g. providing a sub-slab drainage system if needed, during construction.

With no identifiable groundwater issue, the Applicant concluded by arguing that it made little sense therefore to install a sub-slab drainage system for each property.

6. **Respondent's Position**

The Respondent submitted that a drainage system below the slab-on-ground is required as per Article 9.16.3.1. and thus the proposal does not meet Code. He noted that to date the municipality has not been able to conclusively determine whether the soil conditions would require (or not) that a sub-slab drainage system is necessary. Based on this uncertainty about the soil and considering that OBC 9.16.3.1. states that drainage is required "except... where it can be shown to be unnecessary..." (which he indicated has not been proven), the Respondent argued that his interpretation of this Code provision dictates that in the subject circumstance a sub-slab drainage system is required. As he noted, Article 9.16.3.1., in his view, is drafted in such a way as to require a drainage system until it can be proven unnecessary.

Having made the case for the requirement of the drainage system, the Respondent then argued however that he felt this was an example of an excessive requirement found in the Building Code that goes beyond the minimum standards designed to ensure the intended levels of health, life safety, and property protection and barrier-free accessibility. He indicated that he viewed the sub-slab drainage standards as requirements that enhance comfort and quality of construction but are not minimum housing standards.

Nevertheless, he indicated that they have been enforcing the Code as written because that is their responsibility as a municipal building department.

7. **Commission Ruling**

It is the decision of the Building Code Commission that drainage below a slab-on-ground at the Port of Newcastle development in Clarington may be eliminated provided an engineer reports to the Chief Building Official that drainage is unnecessary, or where groundwater levels may cause hydrostatic pressure beneath a floor-on-ground, the floor-on-ground shall be a cast in place concrete slab and designed to resist such pressures.

8. **Reasons**

RULING

1. **The Applicant**

   Mr. Ed Applebaum, Principal, Montgomery Sisam Associates Inc., Toronto, Ontario, has applied for a building permit under

   the Building Code Act, 1992

   to construct a senior's residence known as the Lafontaine Living Centre at 710 Warden Avenue in Toronto, Ontario.

2. **Description of Construction**

   The Applicant proposes to construct a new eight storey high-rise senior's residence with a building area of 2,500 m^2. The structure has been classified as having a Group B, Division 3 - (senior's residential facility) care occupancy. The building will be equipped with fire alarm, standpipe and hose and sprinkler systems and will be of noncombustible construction.

Floors two through eight will contain 27 units each, most of which will be one bedroom suites. All units will be equipped with a kitchenette, livingroom and full bathroom. No nursing stations will be located on these floors. Floors above grade are served by exits stairs at each end of the corridor and a central exit stair. Residents are required to be ambulatory and to provide most of their own care. While each suite will have cooking facilities, the building is to be equipped with dining areas on the ground floor as well. This level will also contain other common areas such as the lounges and special purpose rooms.

There are two areas of construction in dispute. The first is the proposed corridor-based supply system as a means of providing make-up air to the individual residential units. The system proposed by the Applicant is the typical method for supplying air in a residential building in which a pressurized corridor forces certain amounts of air under suite entrance doors, which then provides the make-up air for toilet and kitchen exhaust systems. He is not proposing a make-up air supply system normally found in certain institutional uses.

The second area of construction in dispute are certain paired swing doors, of which one set each is intended for the residential floors and is proposed to be located near the centre of each corridor. Each individual door within a pair are approximately 825 mm (2 ft 8 in) in width. The doors will be hinged near the corridor wall and will not have a centre mullion. With both doors open a clear width of 1,650 mm (5 ft 4 in) is provided. The corridors where the subject paired doors are to be installed are roughly 1.8 m (6 ft) across. The installation of the paired doors will create zones on each floor area. The doors will normally be held open but will release when the fire alarm is activated. In the subject building such zones and doors are not required by Code.

3. **Dispute**

There are two issues at dispute between the Applicant and Respondent. The first is whether the proposed residential-type ventilation system in the subject B3 occupancy complies with Sentence 6.2.3.10.(5) of the Ontario Building Code. This provision permits that a residential occupancy may be supplied with make-up air from a public corridor by pressurizing the corridor. At issue is whether the subject suites can be considered as a residential occupancy and therefore be supplied with this type of ventilation system. While the building has an obvious residential aspect within its function, it has been classified under the OBC as a B3 occupancy. B3 occupancies, as care facilities, are not classified as residential occupancies.

The second dispute is whether the proposed corridor doors, intended for use by ambulatory persons, complies with Sentence 3.3.3.3.(4) of the OBC. This sentence requires that paired doors

in a corridor that serves residents or patients be at least 1,100 mm (3 ft 7 in) in width. The Applicant's proposed doors are only 825 mm (2 ft 8 in) in individual width.

4. **Provisions of the Ontario Building Code**

Sentence 6.2.3.10.(5) Interconnection of Systems

(5) Infiltration due to corridor pressurization is permitted into a residential occupancy from a public corridor.

Sentence 3.3.3.3.(4) Corridors

(4) Paired doors in a corridor serving patients or residents shall

(a) swing in opposite directions, the right hand door swinging in the direction of travel, and
(b) be not less than 1 100 mm (3 ft 7 in) wide.

5. **Applicant's Position**

At the outset the Applicant noted that since the B3 classification is new to the 1997 edition of the OBC the present dispute results from the usual clarification of new Code provisions. In that process of clarifying the B3 classification, he argued that the subject building is more similar to a Group C occupancy than an institutional building. Unlike a Group C occupancy, however, this building will be equipped with a sprinkler system. Regarding both issues at dispute, ventilation and corridor door width, the Applicant submitted that, in his interpretation, they meet Code but he also argued that the proposed design of each provides sufficiency of compliance with the level of safety required by the OBC. He indicated that for both issues he would present arguments concerning interpretation and sufficiency of compliance for the disputed OBC provisions.

On the issue of ventilation, the Applicant submitted that Sentence 6.2.3.10.(5) allows make-up air from a pressurized corridor to enter a "residential occupancy". Significantly, what it does not say, he argued, is that this type of ventilation system is restricted to only Group C major occupancies. In other words, it can be used with any or all residential occupancies, and the suites in the subject building meet the definition of residential occupancies in the OBC, he asserted.

In fact, the Applicant noted that the definition of a Group B, Division 3 - care occupancy was somewhat problematic for the Lafontaine Living Centre. This is because the definition of a B3 occupancy does not include a dwelling unit. However, as the Applicant pointed out, the

individual suites within the building clearly meet the definition of a dwelling unit and, in his view, should be considered as such. In the Applicant's interpretation it was possible to reconcile these definitions by considering the residential floors as having dwelling units and therefore a residential occupancy. By taking this approach, a ventilation system conforming to Sentence 6.2.3.10.(5) should be permitted in the subject building.

In terms of providing sufficiency of compliance of the proposed ventilation system represented a safer design from a fire protection point of view than a standard institutional system in which ducts equipped with dampers supplying make-up air would be required in each suite as well as in the corridor. Recognizing that the suites are the most likely location for a fire to occur, the drawback of this system, the Applicant argued, is that if the balancing of pressure between the suites and the corridor was not maintained, or done correctly, nor operated appropriately in a fire, then smoke could possibly enter the duct system from the suite where the fire originated. Once smoke had contaminated this type of ventilation system it could possibly travel from suite to suite. This scenario would be less likely in his proposed ventilation system since the smoke would have no duct in the suite to penetrate and would have to fill the unit entirely before it could possibly leak out underneath an entrance door and then contaminate the corridor and other suites.

Regarding the proposed corridor swing doors, the Applicant noted that they were not required by Code in either a Group C or B3 occupancy. They were being provided because the building owner felt that creating zones on each residential floor was a safer and more practical approach. The Applicant stated that it was his interpretation of 3.3.3.3.(4) that it applied only to cases where the residents were not, or may not, be ambulatory. He conceded that unfortunately the Sentence does not explicitly state this, nevertheless a close examination of the Code does bear out his position, he argued. He noted that Article 3.3.3.4. required that doorways serving "patients or residents" must be 1,050 mm (3 ft 5 in) except as permitted in Sentence 3.3.1.12.(11). This Sentence, specifically Clause (e), allows corridor doors in a B3 occupancy to be 800 mm (2 ft 7 in). This clearly indicates, asserted the Applicant, that it is not the intent of the Code to require 1,100 mm (3 ft 7 in) wide doors to serve ambulatory residents.

Lastly, the Applicant argued that the proposed door width provides sufficiency of compliance for numerous reasons. For example, he noted that while the corridor is only required to be 1,125 mm (3 ft 8 in) in width the proposed corridor will be 1.8 m (6 ft). However, even at this latter width the corridor could not accommodate a pair of 1,100 mm (3 ft 7 in) doors. The alternative would be to remove the doors entirely, which he reiterated are not required but have been proposed as

an additional safety feature. Wider doors would not make sense in this case, he argued, since the entrance doors to the suites are only 800 mm (2 ft 7 in). Residents have their own furniture and because they are ambulatory they are not moved around in beds, therefore the wider doors to the units and in the corridors are not necessary. Moreover, smaller doors are lighter and as a result easier for the elderly to open, he noted. Because the proposed doors have no centre mullion and a clear opening of 1,650 mm (5 ft 4 in), this would greatly exceed paired doors with a centre mullion which have only 1,050 mm (3 ft 5 in) clear opening. Finally, he indicated that the subject doors also meet the OBC barrier-free standards in terms of required width. For these reasons, the Applicant submitted that the paired swing doors also provide sufficiency of compliance with the OBC.

6. **Respondent's Position**

By way of general comments the Respondent offered that in his view, the classification of the subject building as having a B3 occupancy, meant that a certain albeit limited level of care was being provided to the occupants. As a result, the structure should not be considered as having a residential occupancy.

On the first issue, the Respondent submitted that the proposed ventilation system was not permitted in a B3 occupancy. He argued that it is only allowed in a residential occupancy and therefore Sentence 6.2.3.10.(5) does not apply to the proposed care occupancy.

Concerning the issue of the width of the proposed corridor swing doors, the Respondent noted that they are only 825 mm (2 ft 8 in) and not 1,100 mm (3 ft 7 in) as is required, in his view, for a B3 occupancy under Sentence 3.3.3.3.(4).

7. **Commission Ruling**

It is the decision of the Building Code Commission that the proposed residential type ventilation system in the subject B3 occupancy provide sufficiency of compliance with Sentence 6.2.3.10.(5) of the Ontario Building Code and it is the decision of the Building Code Commission that the proposed 810 mm width of corridor doors intended for ambulatory users provides sufficiency of compliance with Sentence 3.3.3.3.(4) of the Ontario Building Code at the Lafontaine Living Centre, 710 Warden Avenue, Toronto, Ontario.

8. **Reasons**

i) The Building Code Commission is of the opinion that a Group B3 occupancy can include a Group C residential occupancy as defined by the code, provided they meet all of the life safety requirements of a Group B3.

ii) The residents are ambulatory therefore Sentence 3.3.3.3.(4) is not applicable.

RULING

1. **The Applicant**

   Mr. Stefan Hansel, Building Projects Coordinator, Hospice at May Court, Ottawa, Ontario, has applied for a building permit under the *Building Code Act, 1992* to renovate a portion of an existing convalescent home known as the May Court Convalescent Home at 114 Cameron Avenue, Ottawa, Ontario.

2. **Description of Construction**

   The Applicant proposes to undertake interior renovations to an existing convalescent home in order that the home may be converted from a facility that once provided post-surgery recuperative care to one that provides care and comfort programs to terminally ill patients on a day basis. The building is classified as having a Group B, Division 3 - care occupancy. It is described as two storeys, having a total building area of 1,850 m^2, and is of combustible construction. The building will be equipped with a standpipe and hose system and a fire alarm system, but not a sprinkler system.

The subject building is composed of two parts which were built at different times. The original structure is an old two storey (plus basement) converted house that is currently being used as the "Club House"and as staff areas. This part of the building is not currently being renovated. The larger, newer (constructed in 1960) portion of the building, where the renovations are proposed, is a single storey (plus basement) care facility that is connected to the south end of the older building.

As a convalescent home the building originally contained nineteen patient rooms, staff areas, offices, kitchen and dining areas surrounding a central courtyard. As part of converting the convalescent home to a day program care facility many of the rooms will be used for other purposes. Most of the bedrooms, for example, will be converted into offices, treatment rooms, activity rooms, and in some cases a new dining area. (Some bedrooms will remain since in the future the facility may offer overnight accommodations as part of its services.) The existing diningroom will be converted to a lounge equipped with a gas-fired direct vent fireplace.

The construction in dispute involves the placement of a gas-fired fireplace in the proposed lounge. The lounge, centrally situated, also acts as one of the main east-west corridors in the building and is an integral part of its internal circulation system. To allows this east-west movement through the lounge large entrances approximately 2.3 m in width are provided in its east and west walls. The entire south wall of the lounge abuts the courtyard. The fireplace is proposed to be located in the centre of the room's north wall.

3. **Dispute**

The issue at dispute between the Applicant and Respondent is whether the proposed gas-fired fireplace located in the future lounge area which is open to the building's internal corridor system and serves as an access to exit provides sufficiency of compliance with Sentence 3.3.1.2.(3) of the Ontario Building Code. This provision prohibits the installation of a fuel-fired appliance in a corridor that serves as an access to exit. Despite that the northern portion of the lounge functions as a room with a fireplace, the southern half of the lounge is considered an access to exit. At issue is whether the lounge should be viewed as an occupancy located within a corridor. If so, then the proposed fireplace would be deemed to be in a corridor.

While the building is more than five years old and Part 11 can apply to most of its renovation, the inclusion of a fuel-fired appliance in the lounge is, according to Article 11.3.1.2., considered as adding a new building system to the subject structure and therefore must comply with the appropriate new construction standards in the OBC.

4. **Provisions of the Ontario Building Code**

Sentence 3.3.1.2. Hazardous Substances, Equipment and Processes

(3) A fuel-fired appliance shall not be installed in a corridor serving as an access to exit.

5. **Applicant's Position**

While he conceded that the lounge area is to be open to the access to exit, the Applicant submitted that the location of the fireplace is at the most remote point in the room from the exit route and would therefore be less likely to block egress. As a result, he argued that the lounge should not be viewed as an occupancy in a corridor. Moreover, if the fireplace was the source of an uncontrolled fire, he asserted, then exiting would originate from the lounge and would likely be dispersed between the six exits accessible from the north-south corridors immediately to the east and west of the lounge. If the lounge fireplace, the Applicant continued, was not the source of an emergency fire then the lounge would still be able to act as an access to exit route.

Fire separating the northern portion of the lounge to enclose the immediate fireplace area in an effort to maintain a continuous corridor separation would not increase safety nor prevent the spread of fire if the subject appliance were to explode which, in his view, would be the most likely cause of any fire associated with such a unit. An explosion would eliminate any fire containment provided by a drywall and stud separation. Such an event would also possibly render the four exits closest to the lounge unusable, nevertheless the abundance of exits in this building mean that the two more distant exits would still allow egress. However, the Applicant submitted that the potential risk from fire or explosion of the proposed fireplace is minimal. The unit is UL listed, AGA certified, CGA approved and is equipped with a safety switch controlling high temperatures. He argued that the fireplace offers much less hazard than a gas-supplied oven.

By way of offering compensating measures to achieve sufficiency of compliance with Sentence 3.3.1.2.(3) the Applicant proposed to install a shut-off valve which located on the gas line to terminate gas flow to the fireplace when the fire alarm is actuated. He also offered to equip the lounge area with a gas detector and additional smoke detectors, both of which would also be interconnected with fire alarm system.

Lastly, the Applicant stressed the importance of the fireplace to the atmosphere of the hospice. He described it as central element in the communal care and comfort for the hospice users. In his view, the benefit of the fireplace to the spirit and ambiance of the hospice outweighed the small

risks involved. The Applicant submitted a letter from the hospice's Executive Director which stated that "when we considered the move into the May Court building, we had to assure our present patients that there would be a fireplace as that was the most important issue for their approval of the move."

6. **Respondent's Position**

The Respondent submitted that since there is no continuous fire separation for the corridor separating the lounge area and its proposed fireplace then he argued the lounge should be considered as an occupancy in a corridor. He submitted a letter from the Ministry of Municipal Affairs and Housing to support this view. Thus, he therefore considers the proposed fireplace as being located in the corridor which is serving as an access to exit. This, he noted, clearly violates Sentence 3.3.1.2.(3) of the OBC. As a result, he indicated that he does not have the authority to accept the fireplace as proposed by the Applicant. However, he did indicate that he sympathized with the atmosphere the Applicant was trying to create with the fireplace.

7. **Commission Ruling**

It is the decision of the Building Code Commission that the proposed communal fireplace located in a lounge area open to its building's internal corridor system provides sufficiency of compliance with Sentence 3.3.1.2.(3) of the Ontario Building Code at the May Court Convalescent Home, 114 Cameron Avenue , Ottawa, Ontario.

8. **Reasons**

i) A minimum of 4 easily accessible exits are available.

ii) The fuel supply to the fire place is shut off by activation of the fire alarm system or loss of power.

iii) The glass enclosure prevents occupants coming in contact with open flame.

iv) A timing device will limit the use of the fire place to day and early evening use.

v) A system will be in place to avoid excessive heat build up in the room.

RULING

1. **The Applicant**

   Mr. Peter Lesdow, Principal, Peter Lesdow Architect, Niagara Falls, Ontario, has received a building permit under the Building Code Act, 1992 to renovate an existing hotel known as the Renaissance Fallsview Hotel, 6455 Buchanan Avenue, Niagara Falls, Ontario.

2. **Description of Construction**

   The Applicant is currently renovating an existing 17 storey hotel, with a building area of 1,647 m2, and classified as having a Group C (hotel) residential occupancy. The building is of noncombustible construction and is equipped with a sprinkler, fire alarm and standpipe and hose system.

   As part of the work, the Applicant is renovating the existing indoor Class B swimming pool area. In particular, three vertical water supply pipes at the south-east corner of the pool were recently covered with a drywall and steel stud wall. The water pipes were installed to supply water to a decorative fountain that flows into the pool and is mounted on the north wall of the pool room.

The construction in dispute relates to the reduced width of the pool deck that would result from the addition of the furred in covering wall. Where the new wall is to be installed, for a total of 4.5 m (14 ft) of the total 42 m (137.8 ft) perimeter of the pool, the pool deck would be reduced. At its narrowest point the pool deck would be reduced to 1,675 mm.

3. **Dispute**

The issue at dispute between the Applicant and Respondent is whether the as constructed pool deck width of 1,675 mm (5 ft 6 in) provides sufficiency of compliance with Clause 3.11.3.1.(9)(a) of the Ontario Building Code. This provision requires that for this type of pool decks must be a minimum of at least 1,800 mm (5 ft 11 in) in width. The pool deck is currently 125 mm narrower than the minimum allowed width.

4. **Provisions of the Ontario Building Code**

Clause 3.11.3.1.(9)(a) Construction Requirements

(9) Except for a modified pool and wave action pool and except as provided in Sentence (11), a public pool shall be surrounded by a hard-surfaced pool deck that shall

(a) except for a pool described in Sentence 3.11.5.1.(1), be not less than 1 800 mm (5 ft 11 in) wide and provide at least 900 mm (2 ft 11 in) width of clear passage,

(i) behind any diving board and its supporting structure, and
(ii) between any column piercing the deck and the edge of the pool or between the column and outer perimeter of the pool deck,

5. **Applicant's Position**

While conceding that the pool deck does not meet the minimum deck width requirements, the Applicant submitted that it does provide sufficiency of compliance with Clause 3.11.3.1.(9)(a). He argued that because the worst of the infraction occurs at the corner of the pool where the diagonal measurement is much greater than 1,800 mm (5 ft in) there is adequate space for rescue operations. As a result, he submitted that the pool deck met the intent of the Ontario Building Code.

Moreover, the Applicant argued that the Code allows columns to exist within 4 ft of the pool edge. These, he noted, reduce deck width to a greater extent than the present situation.

Finally, the Applicant indicated that short of removing the disputed wall little can be done to increase the deck width. He did, however, offer to post a sign at the location noting the narrower deck and to install an addition rescue pole.

6. **Respondent's Position**

The Respondent submitted that the Clause 3.11.3.1.(9)(a) of the OBC requires that pool decks have a minimum width of 1,800 mm (5 ft 11 in). The existing situation, he noted, reduces the clear width of the deck by 125 mm (4 1/2 in). The Respondent argued that the 1,800 mm width was necessary to prevent accidental falling into the pool as users pass each other on the deck surface and it also provides adequate space for rescue operations. As a result, he viewed the 1,800 mm pool deck width as a required minimum. For this reason, the Respondent indicated that he could not accept the reduced the pool deck width.

7. **Commission Ruling**

It is the decision of the Building Code Commission that the pool deck width of 1,675 mm (5 ft 6 in) provide sufficiency of compliance with Sentence 3.11.3.1.(9)(a) of the Ontario Building Code at the Renaissance Fallsview Hotel, 6455 Buchanan Avenue, Niagara Falls, Ontario.

8. **Reasons**

i) The applicant has agreed to provide an additional rescue pole.

ii) Adequate ceiling height, is available for manipulation of the rescue pole.

RULING

1. **The Applicant**

   Mr. John Martini, Site Supervisor, Bayview Wellington Homes, Woodbridge, Ontario, has received a building permit under the Building Code Act, 1992 to construct a subdivision of residential dwelling units at Bridgeport Drive, Toronto, Ontario.

2. **Description of Construction**

   The Applicant has recently constructed a subdivision of new two storey townhouse units classified as Group C - residential occupancies. As part of the construction the Applicant installed certain casement windows (known as the Tudor model) manufactured by Pollard Windows Inc. in the bedrooms of the subject townhouse units. The subject windows measure 600 mm (23 5/8 in) in width and are variable heights. In terms of its operation, the hinge, or rotation pins, at the top and bottom of the casement window unit which fasten the window to its frame and upon which it swings slide toward the vertical centre-line of the window opening.

   The construction in dispute relates to the fact that when the subject windows are opened to an angle of 900 as measured from the exterior wall the width of clear opening is reduced to

approximately 356 to 362 mm (14 to 14 3/8 in) due to the shift towards centre of the rotation pins. During opening of the window, while at an angle ranging from 600 to 750, a clear opening width of 380 mm (15 in) is achieved. The height nor the total unobstructed open area of the casement windows are in dispute.

3. **Dispute**

The issue at dispute between the Applicant and Respondent is whether the as built unobstructed open width portion of the window, at 356 mm (14 in), complies with Clause 9.7.1.3.(1)(b) of the Ontario Building Code. This provision requires that no window that is to be used as an alternative access to the exterior have a dimension less than 380 mm (15 in). The Applicant's Tudor casement window, when opened 900, only has a clear, unobstructed opening of 356 mm (14 in). When opened less than 900, however, the minimum clear width of 380 mm (15 in) is provided. Clause 9.7.1.3.(1)(b) is silent on whether the minimum opening dimension is required at 900 as measured from the exterior wall of the building containing the window.

4. **Provisions of the Ontario Building Code**

Article 9.7.1.3(1)(b) Bedroom Windows

(1) Except where a door on the same floor level as the bedroom provides direct access to the exterior, every floor level containing a bedroom in a suite shall be provided with

(a) at least 1 outside window that can be opened from the inside without the use of tools, and

(b) each such window shall provide an individual, unobstructed open portion having a minimum area of 0.35 m2 (3.8 ft2) with no dimension less than 380 mm (15 in).

5. **Applicant's Position**

The Applicant submitted that the subject windows comply with Clause 9.7.1.3.(1)(b) of the OBC. He argued that the windows do provide the minimum clear width of 380 mm (15 in) when opened between 600 and 750. He noted that no where in Clause 9.7.1.3.(1)(b) does it stipulate that the minimum dimension must be achieved with the window open 900. Moreover, the associated OBC Appendix reference does not provide such a specification either. If this is the Code's intent, he suggested, this could be a useful revision in the future.

The Applicant indicated that, in fact, the subject windows provide more than the minimum 380 mm (15 in) when in the almost fully open position. He also noted that the height and the total area requirements were easily met. Therefore, in his view, the performance of the casement windows met the secondary access intent of Clause 9.7.1.3.(1)(b) of the Code.

The Applicant did offer that if the BCC ruled against them they would change their production immediately. Specifically, he indicated that he could replace the hinges on this model to allow for the full 380 mm (15 in).

6. **Respondent's Position**

The Respondent submitted that the casement windows in dispute do not meet the unobstructed opening requirements found in Clause 9.7.1.3.(1)(b). As he noted, this provision requires 380 mm (15 in) and the windows, when fully open, only have a clear width of 356 mm (14 3/8 in). This, he argued, clearly does not meet Code. He indicated that measuring the opening at something less than 900 was not consistent with the principles used in the OBC. He cited the examples of corridors and doors which are not measured in the Code on anything less than 900 with respect to the direction of path of travel.

The Respondent also indicated that he was concerned that the subject windows represented a further reduction in egress window width. He noted that previous versions of the Code had width criteria up to 500 mm (19 3/4 in). As well, he was concerned that the reduced window width may be problematic with respect to accessibility to or from a ladder. Without being able to open the window to 900, he argued, meant that getting out of a house and onto a ladder for occupants escaping a fire or getting into a house from a ladder by a firefighter would be made more difficult.

Because the subject windows cannot provide a minimum of at least 380 mm (15 in) for all dimensions, in his view, therefore they do meet the intent of OBC 9.7.1.3.(1)(b) in terms of ensuring alternate access.

7. **Commission Ruling**

It is the decision of the Building Code Commission that the unobstructed open width portion of the casement windows does not comply with Clause 9.7.1.3.(1)(b) of the Ontario Building Code at the Bridgeport Drive Subdivision, Toronto, Ontario.

8. **Reasons**

(i) The window as constructed does not meet the intent of Clause 9.7.1.3.(1)(b).

(ii) In regards to the intent of the Code with respect to the egress provisions it is likely that in an emergency situation the window will be in its fully open position, and therefore, not meet the minimum requirements of Clause 9.7.1.3.(1)(b).

(iii) In regard to the intent of the Code with respect to the ingress provisions the window sash must be in less than a fully open position, to meet the minimum requirements of the Code, therefore, the sash represents a hazard to the safe positioning of a ladder.

9. **Recommendations**

The Building Code Commission recommends that consideration be given to changing the Code to that of the Article 9.7.1.3. of the 1986 Code.

APPEARANCES

Mr. Greg Sperry, Owner
Sperry Construction Ltd.
Ennismore, Ontario
The Applicant

RULING

1. **The Applicant**

   Mr. Greg Sperry, Sperry Construction Ltd., has applied for a building permit under *the Building Code Act, 1992* to construct a new garage on the Poutney seasonal property at 1434 Eastview Drive, Smith-Ennismore Township, Ontario.

2. **Description of Construction**

   The Applicant proposes to build a one storey, 4.88 m by 6.1 m (16 ft by 20 ft), wood frame 2 car garage with poured concrete foundation walls situated in the south corner of the subject triangular property. The length of the garage would run roughly parallel to and less than a metre from the north-east lot line, while the width of the garage (with the car entrance) would be set on an angle from the street access off Eastview Drive. The nearest corner of the garage face would be 1.66 m (5 ft 6 in) to the street and the far corner would be 5.87 m (19 ft 3 in) away. The existing seasonal dwelling is located approximately in the centre of the subject property, behind and to the north of the proposed garage. To the north of the dwelling is a lake.

   The construction in dispute involves the lack of adequate clearance distance between the north-west wall of the proposed garage and the south-east corner of an existing holding tank. The clearance, as proposed, is only 150 mm (6 in). The 9,000 litre holding tank measuring 2.13 m by

4.14 m (7 ft by 13 ft 7 in) runs lengthwise with the north-south lot line and is set back roughly 1.22 m (4 ft). Between the dwelling and the holding tank 3.05 m (10 ft) clearance is provided.

3. **Dispute**

The issue at dispute between the Applicant and Respondent is whether the new garage, proposed to be situated with a set back of 150 mm from the existing holding tank, provides sufficiency of compliance with Article 8.2.1.6. of the Ontario Building Code. This provision, specifically Table 8.2.1.6.C., requires that a minimum clearance separation of 1.5 m be provided between a holding tank and a structure. The Applicant, with his proposed garage location, is providing only 150 mm, or 0.15 m, clearance to the existing holding tank.

4. **Provisions of the Ontario Building Code**

Article 8.2.1.6.(1)(b) Clearances for a Class 4 or 5 Sewage System

(1) Except as provided in Sentences 8.2.1.4.(1) and (2), a treatment unit shall not be located closer than the minimum horizontal distances as set out in Table 8.2.1.6.A.

(2) Except as provided in Sentences 8.2.1.4.(1) and (2), a distribution pipe shall not be located closer than the minimum horizontal distances set out in Table 8.2.1.6.B. and these distances shall be increased when required by Sentence 8.7.4.2.(9).

(3) No building shall be constructed closer to any part of a sewage system than the clearances listed in Articles 8.2.1.5. or 8.2.1.6.

5. **Applicant's Position**

The Applicant submitted that the proposed garage is sited in the best possible location considering the serious constraints of the site such as the unusual shape of the property and the pre-existing location of the holding tank and the dwelling. He also argued that servicing of the holding tank was quite possible even in the proposed location.

Even though it was installed less than five years ago the Applicant offered to move the holding tank by rotating it so that its length runs parallel to the proposed garage and its rear width runs parallel to the front of the dwelling. This option would provide the required 1.5 m setback between the holding tank and the proposed garage and the dwelling. The drawback of this option however, admitted the Applicant, is that it would not meet the clearance distance required

between the holding tank and the lot line, the distance available would be less than a metre whereas the Code requires 3 m.

The Applicant also offered to change the foundation wall adjacent to the holding tank to one of concrete piers supporting structural beams. The piers, he proposed, could be set back from the corner of the holding tank so that the clearance distances would be met and that no structural problems would result.

6. **Respondent's Position**

The Respondent submitted that the proposed garage location does not meet Article 8.2.1.6. of the OBC. In fact, he argued that a set back of 150 mm is a serious reduction of the required clearance distance of 1.5 m. For this reason, he felt he could not approve the construction of the garage.

The Respondent did acknowledge the extreme site constraints faced by the Applicant. He noted that even the existing holding tank, approved by the Ministry of the Environment, does not meet the current OBC standards for clearance distances.

7. **Commission Ruling**

It is the decision of the Building Code Commission that the 0.15 metre set back from the proposed garage to the existing holding tank provides sufficiency of compliance with Article 8.2.1.6., provided that a consulting engineer design the structural support for the garage to ensure that the supports are a minimum of 1.5 m from the tank.

8. **Reasons**

(i) The holding tank, although not meeting the existing set back requirements to the lot line was installed with the approval of the appropriate agency.

(ii) The proposed garage is to be constructed without a foundation weeper which will negate any opportunity for the discharge of subsurface leakage to the surface.

(iii) The supporting structure for the garage will be a minimum of 1.5. metres from the holding tank.

(iv) Provided the tank is exposed to confirm its location and construction of the garage is undertaken carefully without construction equipment travelling on the tank, the position of the garage close to the tank will not impact on the performance of the tank.

(v) There is an opportunity to access the holding tank location in the event that the tank must be repaired or replaced.

RULING

1. **The Applicant**

   Mr. Rick Hudson, Owner, Hudson Motorcycles Inc., Wheatley, Ontario, has received a building permit under the *Building Code Act, 1992* to install a new Class 4 sewage system at Part Lot 19, Concession IV, Township of Lakeshore, Essex County, Ontario.

2. **Description of Construction**

   The Applicant is proposing to install a new Class 4 conventional sewage system with a fully raised leaching bed to serve a proposed, 327 m^2, Group E - mercantile (retail) occupancy. The proposed building is to contain six employees and will have less than 20 fixture units (12.5). The calculated total daily design sewage flow rate, based on 75 litres/per day/per employee, is 450 litres per day.

   The proposed new sewage system would consist of a 3,600 litre septic tank (the minimum size allowed under OBC) that would receive effluent from the motorcycle retail operation, which

would then be transmitted to a pump chamber, equipped with float operated high level alarm. The effluent would move through these components of the system by means of gravity disposal. From the pump chamber, however, it would be pumped up into the raised trenches of the disposal bed where it would be time dosed at 262 L/dose.

The fully raised disposal bed, necessary due to the presence of clay at grade, will be set back 5 m from the proposed building and will be constructed of imported sand with a percolation rate ranging from approximately 1 to 8 minutes per centimetre set on scarified native clay. The proposed raised bed is to have an area of 349 m^2 (25.5 m by 13.7 m) and will be 1.5 m in height. With a total hydraulic footprint, or contact area, of 349 m2 and a daily flow rate of 450 L/d, the application, or loading, rate is calculated at roughly 1.29 litres/m^2/day.

Using the T-time of 8 min/cm of the imported fill and the a daily flow rate of 450 L/d, the length of required distribution pipe was calculated to be only 18 m, but will be increased to at least 40 m to meet the minimum length of leaching tile required as per the OBC. The distribution pipe will be laid out in three parallel 15 m trench runs set at depth of 900 mm above the native clay. The trenches will be located 1.6 m apart on centre, while the 1:4 slope surrounding the raised bed will commence at distance of 1 m from the perimeter of the trenches.

The site measures 174.3 m by 103.6 m and is extremely level. The native soil is described as clayey and has a T-time of greater than 50 minutes per centimetre.

The subject dwelling is served by a well water system.

The Construction in dispute is that the Applicant is proposing to construct the subject fully raised leaching bed without a mantle in any direction. The Applicant had previously received a permit for the installation of a raised bed with a 15 m mantle in all directions but is now seeking a revision to that permit to exclude the mantle entirely.

3. **Dispute**

The issue at dispute between the Applicant and Respondent is whether, when considering an adequate daily loading rate, the Class 4 sewage system proposed without a 15 m mantle provides sufficiency of compliance with Clause 8.7.4.2.(1)(b) of the Ontario Building Code. This provision of the Code requires that a 15 m mantle be constructed in any direction that effluent may move horizontally in the soil. The intent of this requirement is to ensure that the area of

unsaturated soil (to a depth of 250 mm) extends beyond the raised portion of the leaching bed, especially in the direction of gravitational flow.

Since the subject site is considerably flat, it is conceivable that effluent may move, according to the Applicant, in any direction from the distribution pipes. The Applicant has interpreted this to mean that a 15 m mantle is required in all directions. A surrounding mantle was included in the original application. The mantle, however, has been completely excluded from the current proposal since the Applicant deems that the loading requirements of Sentence 8.7.5.2.(2) are being met using only the hydraulic footprint of the raised bed itself.

4. **Provisions of the Ontario Building Code**

Clause 8.7.4.2.(1)(b) Construction Requirements

(1) A leaching bed comprised of absorption trenches may be constructed in leaching bed fill provided that the unsaturated soil complying with Clause 8.7.2.1.(1)(b) extends

(b) for at least 15 m beyond the outer distribution pipes in any direction in which the effluent entering the soil will move horizontally.

5. **Applicant's Position**

The Applicant submitted the proposed leaching bed, without a mantle, provides sufficiency of compliance with Sentence 8.7.4.2.(1) of the Code. He argued that, when considering the small daily design flow rate of 450 L/d for the subject occupancy and the required 40 m minimum length of distribution pipe (although 45 m are being proposed), the approximate application rate of 1.29 litres/m^2/day for just the raised bed alone was already on the low side. Having to provide a mantle in any direction let alone in every direction, in his view, was therefore highly unnecessary. He indicated that the imported fill of the raised bed could more than adequately absorb the effluent produced. The exclusion of the mantle, especially a surrounding mantle, the Applicant noted would allow proponents to considerably reduce the required building materials as well as the overall costs of the project.

The Applicant argued that the Building Code should allow sewage systems to be designed on the basis of application rates and their respective contact areas. By allowing systems to be based on their actual daily flow rates and the true filter medium necessary would allow, he asserted, for more appropriately designed systems that better fit the intended use of the associated occupancy.

It would also prevent the construction of "overbuilt" systems such as the case at hand which, the Applicant argued, resulted from certain "minimum requirement" standards being triggered in the Code.

6. **Respondent's Position**

The Respondent submitted that the subject sewage system proposed without a 15 m mantle simply does not comply with the Code, in particular Clause 8.7.4.2.(1)(b). He argued that a mantle in the direction of flow is a necessary feature of raised bed systems that enables their proper functioning by increasing the contact area. The mantle also provides additional levels of safety in the event that the bed fails. The Respondent noted that a mantle has been a long standing requirement of such raised beds. He indicated that he believed he did not have the authority to allow what, in his view, is a large deviation from the requirements of the Code.

7. **Commission Ruling**

It is the decision of the Building Code Commission that the proposed 4.3 metres of leaching bed fill down gradient of the distribution pipe does not provide sufficiency of compliance with Clause 8.7.4.2.(1)(b).

8. **Reasons**

(i) A 15 m mantle is required as per Clause 8.7.4.2.(1)(b).

(ii) No evidence was provided that the native soil meets the requirements of Subclause 8.7.2.1.(1)(b)(ii).

RULING

1. **The Applicant**

   Mr. Melvin Dreger, President, 1088416 Ontario Inc., Lindsay, Ontario, has applied for a building permit under the *Building Code Act, 1992* to renovate and expand an existing seniors residence, as well as to enlarge the Class 4 sewage system at the Country Estates Retirement Home, 512 Thunderbridge Road, Lindsay, Ontario.

2. **Description of Construction**

   The Applicant is proposing to renovate an existing, 13 occupant, structure with a total finished area of 566.9 m^2 currently classified as a Group C - residential (senior's boarding house) occupancy by adding an additional 223 m^2 of finished area. The building when completed would have a total finished area of roughly 769.9 m^2, approximately 45 fixture units, an increased occupant load of up to 32 persons, and would possibly be classified as either a Group B, Division 2 - care and treatment (nursing/rest home) occupancy, or as a Group B, Division 3 - care (convalescent/residential care facility) occupancy.

As part of the renovation and expansion of the existing facility, the Applicant is also proposing to expand his existing Class 4 sewage system to service the enlarged building. The current system consists of a 4,500 litre septic tank connected to two conventional leaching beds, the smaller of which serves four persons and is located to the north-east of the existing building. This bed is not in dispute. The larger bed, with 220 m (eight runs of 27.5 m) of distribution pipe, is situated to the north-west of the senior's boarding house.

The Applicant has conducted a study measuring the actual water consumption in the existing building and has calculated total daily design sewage flow rate at 230 litres/person/day. (This figure includes a certain safety margin - the actual measured amount was 195 L/p/d.) He has designed his proposed system based on this calculated output.

The proposed enlarged sewage system would consist of an additional 14,000 litre septic tank connected to two new pump chambers with each pump equipped with floatation alarm devices. The effluent would move through these components of the system by means of gravity disposal. From the pump chamber, however, it would be mechanically pumped into the trenches of the disposal beds. Two additional leaching bed areas would be created, one to the north-west of the existing building, and one to the south-west. The new north-west bed would contain 17 runs of 29 m for a total of 493 m of distribution pipe. The south-west bed would be comprised of 12 runs of 29 m for a total of 348 m. Including the existing leaching bed areas, the total expanded area would be 1,061 m (not including the smaller undisputed existing bed).

The new disposal beds will be constructed of imported sand set in trenches 600 mm deep spaced 2 m apart on centre. The percolation rate of the native soil is approximately 40 minutes per centimetre.

The site is described as level and covered with grass. The high groundwater table is located at approximately 600 mm below the surface.

The subject dwelling is served by a well water and cistern system.

3. **Dispute**

The issue at dispute between the Applicant and Respondent is whether the proposed enlargement of the Class 4 sewage system based on current measured daily design sewage flow rates to serve an expanded nursing home provides sufficiency of compliance with Article 8.2.1.3. of the Ontario Building Code. This provision sets out the prescribed daily sewage system design flow

rates for various building occupancies. For Group C - residential occupancies, including boarding houses - the building's current use, the daily design flow rate is 240 L/p/d. However, for both Group B, Division 2 - care and treatment occupancies which includes homes for the aged and nursing homes, and Group B, Division 3 - care occupancies which encompasses convalescent homes and residential care facilities, the daily flow rate is 450 L/p/d. Determining the type of occupancy is normally a crucial first step in designing the required sewage system for any building. The Applicant has, nonetheless, designed his system based on the actual measured daily sewage flow.

4. **Provisions of the Ontario Building Code**

Article 8.2.1.3. Sewage System Design Flows

(1) For residential occupancies, the total daily design sanitary sewage flow shall be at least the value in Column 2 as determined from Table 8.2.1.3.A.

(2) For all other occupancies, the total daily design sanitary sewage flow shall be at least the value in column 2 as determined from Table 8.2.1.3.B.(See Appendix A.)

(3) Where a building contains more than one establishment, the total daily design sanitary sewage flow shall be the sum of the total daily design sanitary sewage flow for each establishment.

(4) Where an occupancy is not listed in Table 8.2.1.3.B., the highest of metered flow data from at least 6 similar establishments shall be acceptable for determining total daily design sanitary sewage flow.

5. **Applicant's Position**

The Applicant submitted that their proposed use does not neatly fit within existing classifications in the OBC. He argued that the proposed structure will function much like the current building, which is a 13 person residential boarding house occupancy, only on a larger scale. In his view, the B2 and B3 occupancies imply that a certain degree of care and treatment will be offered to inhabitants. However, in retirement homes generally and in his operation in particular, the Applicant indicated that the usage is more appropriately described as residential in nature with meals and laundry services provided. This, he argued, is more in keeping with other Group C uses such as hotels, boarding schools and boarding houses.

The Applicant also noted that it was not feasible for him to determine the daily design sewage flow as per Sentence 8.2.1.3.(4) of the OBC, which allows a calculation based on the highest metered flow taken from three similar establishments since historic information from other sources was lacking.

Regarding the prescribed 450 litres per day as set out in the B2 and B3 classifications, the Applicant indicated that he thought it was onerous and does not reflect the type of usage for retirement homes. He argued that even though the occupant load only increases by two to two and a half times, by virtue of the fact that the building is being reclassified from residential to B2 or B3 the required size of the proposed bed increases by six or seven times the size of the existing bed.

The Applicant argued that by basing the design of the system on the actual flow rates a very rationale and appropriately sized sewage system gets built. The measurements show the actual water intake which provides an accurate indicator of the sewage output. This measurement is then increased by five to ten litres to take into consideration food and bottles/tins of liquids consumed by residents that were purchased off-site. He noted that the flow measurement device is hard connected to the plumbing system. As a result, it can provide close, long term monitoring of water intake and the resultant effluent output. The Applicant offered to make these monitoring results available to the local authorities.

Lastly, the Applicant stated that the figure used to calculate the size of the leaching bed already included a safety margin of roughly 30 L/p/d. This cushion would provide room for increased water use by the future residents, or it may allow for more residents, up to 32, to occupy the expanded building and still be within the capacity of the proposed sewage system. He reiterated that even though the building may be expanding, the way the current and future occupants use it will remain the same, including the amount of effluent created. That amount, as it does now, will fall well within the daily design sewage flow for boarding houses.

6. **Respondent's Position**

The Respondent submitted that the proposed expanded senior's residence should be properly classified as a B2 occupancy. As he noted, because some of the residents would require assistance to exit the building in the event of an emergency the proposed occupancy should be seen as a facility providing a degree of care. He argued that it cannot be viewed as a large boarding house. From this classification, the relevant Code provisions are clear. The daily design

sewage flow rate is 450 L/p/d and the proposed enlargement of the sewage system must be sufficient to adequately handle this additional capacity.

The Respondent also indicated that, in his view, the Code did not give him the authority to accept a sewage system designed on the basis of a measurement of current output.

7. **Commission Ruling**

It is the decision of the Building Code Commission that the total daily design sanitary sewage flow for the proposed expanded retirement home, as calculated by Table 8.2.1.3.B, is 14,400 litres per day.

Under Clause (F) of Article 1.1.3.2. (as amended by Regulation 278-99), this proposed system fails the definition of a sewage system. Accordingly, the approval of the system design is the responsibility of the Ministry of Environment.

RULING

1. **The Applicant**

   Mr. Maurizio Bartucci, property owner, has applied for a building permit under the *Building Code Act, 1992* to change the use of an existing industrial building to a mercantile occupancy and to also undertake interior renovations at Country Garden Concrete, 9593 Highway 124, Erin, Ontario.

2. **Description of Construction**

   The Applicant is proposing to change the use of an existing industrial building that was formerly used for the storage of farm machinery, septic tank pumping trucks and backhoes to a mainly Group E - mercantile (display, retail and wholesale) occupancy that will be used for the sale of concrete garden products, such as bird baths, fountains, statutes, flower pots, etc. Roughly one fifth of the floor area of the subject building will be considered a Group F - Division 2 (manufacturing) occupancy devoted to the production of the concrete garden products.

The existing building is described as one storey with a building area of 393.6 m^2 and having dimensions of 16.8 m by 23.5 m. The structure has exterior walls composed of 300 mm thick concrete on all four sides. A wood frame supports the corrugated steel roof sheathing. At the long sides of the building the roof framing rests upon the concrete walls, at the gable ends wood studs clad with corrugated metal siding support the roof assembly.

The Applicant is also proposing to renovate the subject building by constructing interior partitions to create specific areas within the building and by cutting an opening in the existing concrete wall at the east end to provide a 925 mm wide door as an additional exit. Among the new spaces created by the proposed interior partitions would be a production area of roughly 72.5 m^2 that would be covered with a wood frame ceiling. The walls for this area would be supported by three 2 by 4 wood stud columns stabilized by eight 300 mm concrete piers set on undisturbed soil placed around the perimeter of the production area. The ceiling of this area would also be supported by two of the same stud columns on the same concrete piers located roughly in the middle of the production area. Identically constructed partition walls would also provide an uncovered 50.1 m^2 storage area, and a small washroom. The total interior area of the building that would be enclosed by the proposed partitions is 128.1 m^2.

The construction in dispute involves the existing gravel floor of the building. The Applicant is not proposing to replace it with a concrete slab on ground, except in the small proposed washroom.

3. **Dispute**

The issue at dispute between the Applicant and Respondent is whether, considering the proposed change of use and interior renovations, the existing gravel floor is required to comply with Sentences 4.1.1.3.(1) and 4.1.1.7.(1), Article 3.8.1.3., and Sentences 3.8.2.1.(1) and 9.9.5.5.(2) which collectively deal with certain structural, barrier-free, obstruction of means of egress, dampproofing and soil gas control standards. If deemed necessary that the current gravel floor must meet some or all of the referenced standards then a poured structural concrete floor slab may be required.

4. **Provisions of the Ontario Building Code**

Sentence 4.1.1.3.(1) Design Requirements

(1) Buildings and their structural members including formwork and falsework shall be designed to have sufficient structural capacity and structural integrity to resist safely and effectively all loads and effects of loads and influences that may reasonably be expected, having regard to the expected service life of buildings, and shall in any case satisfy the requirements of this Section. (See Appendix A.)

Sentence 4.1.1.7.(1) Stability

(1) Provision shall be made to ensure adequate stability of a structure as a whole, and adequate lateral, torsional and local stability of all structural parts.

Article 3.8.1.3. Barrier-Free Path of Travel

(1) Except as required in Sentence (4) and except as permitted in Subsection 3.8.3., every barrier-free path of travel shall provide an unobstructed width of at least 1 060 mm (3 ft 6 in) for the passage of wheelchairs.

(2) Interior and exterior walking surfaces that are within a barrier-free path of travel shall
(a) have no opening that will permit the passage of a sphere more than 13 mm (? in) in diam,
(b) have any elongated openings oriented approximately perpendicular to the direction of travel,
(c) be stable, firm and slip-resistant,
(d) be bevelled at a maximum slope of 1 in 2 at changes in level not more than 13 mm (? in), and
(e) be provided with sloped floors or ramps at changes in level more than 13 mm (? in).

Sentence 3.8.2.1.(1) Areas Requiring Barrier-Free Path of Travel

(1) Except where essential obstructions in the work area would make a barrier-free path of travel hazardous, and except as provided in Sentences (2), (3) and (4), a barrier-free path of travel from the entrances required by Sentences 3.8.1.2.(1) and (2) to be barrier-free shall be provided throughout the entrance storey and within all normally occupied floor areas served by a passenger type elevator or other platform equipped passenger elevating device.

Sentence 9.9.5.5.(2) Obstructions in the Means of Egress

(2) Except as provided in Sentence (3), no obstructions, such as counter gates, which do not meet the requirements for exit doors, shall be placed in a required means of egress from a floor area or part of a floor area unless an alternate unobstructed means of egress is provided adjacent to and plainly visible from the restricted egress.

5. **Applicant's Position**

The Applicant submitted that the present gravel floor is suitable for the proposed use, that the numerous OBC provisions cited do not apply, and thus a concrete floor is not necessary. The existing gravel floor was never part of the building permit application, therefore he could not understand why any of the disputed provisions would apply. He then dealt with the issues raised by the Respondent one at a time.

Regarding the structural requirements found in Part 4 of the Code, the Applicant provided a letter from an engineer stating that the gravel floor is capable of supporting a uniform load of 4.8 kPa, which he indicated is what is required for this type of use. He then noted that even in the production area the loading will not approach anywhere near 4.8 kPa. The Applicant rejected the idea that a structural concrete floor slab was necessary, after all he noted, the building has stood for several decades without such a floor slab.

On the issue of barrier-free accessibility, the Applicant indicated that he did not believe that Section 3.8 applied to this building. His reading of the disputed barrier-free OBC provisions, especially Article 3.8.1.3., was that no where do they stipulate that a concrete floor is necessary in order to achieve compliance.

Insofar as preventing an obstruction of the means of egress as found in Sentence 9.9.5.5.(2) is concerned, the Applicant argued that the existing gravel floor, while not as perfectly flat as concrete, is quite level. He indicated that the floor would not be a tripping hazard in the event of a quick exit due to an emergency. Further, the Applicant argued that the intent of Sentence 9.9.5.5.(2) was to prevent large objects like a gate from being placed in an egress route.

Lastly, the Applicant indicated that he is satisfied with the current gravel floor. In his view, none of the aforementioned Code provisions apply. A concrete floor would be an unnecessary and wasteful expenditure. The current gravel floor will not reduce the performance level of the building.

6. **Respondent's Position**

The Respondent submitted that the gravel floor is inadequate and that a structural concrete floor slab is necessary for several specific reasons.

He began by stating that according to Part 10 of the OBC the performance level of the building will be reduced due to increased occupant load with people working in the building for long periods of time and also with public access to the structure.

The Respondent continued by arguing that, in his view, enough changes were being made to the building with the interior partitions, one of which supports a ceiling, and the cutting of the exterior concrete wall for a door that OBC Articles 4.1.1.3. "Design Requirements" and 4.1.1.7 "Stability" would apply. He argued that a structural concrete floor would provide the necessary stability and would offset any of proposed changes to the building. The gravel floor, he noted, is not a stable element.

Secondly, the Respondent noted that the non-level and uneven gravel floor could be a problem for able-bodied persons as well. In his view, the gravel floor presents a tripping hazard that could possibly impede a person's means of egress, especially in the event of an emergency. Sentence 9.9.5.5.(2), he argued, specifically prohibits any obstacles in the means of egress and this could also be construed as an uneven gravel floor.

Lastly, the Respondent indicated that it was his belief that a barrier-free accessible path of travel is necessary. In his view, the barrier-free accessibility requirements found in Section 3.8 mandated that a concrete floor was necessary to assist the movement of people in wheelchairs. He expressed concern about the uneven gravel floor and the reduced mobility it would cause. Even if it is not required, he argued that it would certainly provide a higher level of comfort and freedom of movement for disabled persons.

For these reasons, the Respondent concluded by stating that a concrete slab is required in order to maintain the building's performance level.

7. **Commission Ruling**

It is the decision of the Building Code Commission that the existing ground floor is not necessary to comply with Sentences 4.1.1.3.(1) and 4.1.1.7.(1), Article 3.8.1.3., and Sentences 3.8.2.1.(1) and 9.9.5.5.(2) of the Ontario Building Code at Country Garden Concrete 9593 Country Highway 124 Erin, Ontario.

8. **Reasons**

i) According to Article 2.1.1.7. and consideration of Part 11, Section 11.4. (performance level evaluation and compensating construction), there is no reduction in performance with respect to the existing ground floor.

ii) Article 3.8.1.3. does not mandate that a concrete slab-on-grade must be provided.

RULING

1. **The Applicant**

   Ms. Elizabeth Lavery, Facility Manager, has received a building permit under the *Building Code Act, 1992, to construct a head office building to accommodate the Ontario Ministry of Agriculture, Food and Rural Affairs at 1 Stone Road West, Guelph, Ontario.*

   Ms. Elizabeth Lavery, Facility Manager, Ontario Realty Corporation, 1 Stone Road West, Guelph, Ontario, for the resolution of a dispute with Mr. Bruce Poole, Chief Building Official, City of Guelph, Ontario to determine whether the travel distances on the second to fifth floors ranging from 53 to 56 m, in a structure with interconnected floor space due to the full height atrium, provides sufficiency of compliance with Sentence 3.2.8.4.(4) and Clause 3.4.2.5.(1)(b) of the Ontario Building Code at the OMAFRA Head Office building, Guelph, Ontario.

2. ***Description of Construction***

The Applicant has recently constructed a new, six storey, Group D - business occupancy (office), with a building area of 12,000 m^2. The building will be of noncombustible construction and will be equipped with a sprinkler system, fire alarm system and standpipe and hose system.

An atrium separating the building into north and south wings extends from the ground floor to the fifth. The atrium creates an interconnected floor space. Both wings on floors two to five are served by three exits each, except for the north wing on the second floor which has four exits. The occupant load per floor ranges from 688 persons on the second floor to 479 on the fifth. On each floor the north wing contains a somewhat higher occupant load than the south wing.

The construction in dispute involves the travel distances on the second to fifth floors, which from the most remote areas on these levels ranges from 53 to 56 m (13 to 16 m beyond the permitted distance). The travel distances on all interconnected north wing floors are 53 m. In the south wing the travel distances on the second, third and fourth floors are 55 m, whereas the fifth floor travel distance is 56 m.

Travel distances became an issue when partitions and furniture were installed in the recently completed building. The floor areas had originally be designed and built as open floor areas. The travel distances had been calculated on a straight line basis from the most remote point to the nearest exit. With the furniture and partitions the egress routes were no longer straight and therefore increased beyond the maximum allowed in the OBC.

3. ***Dispute***

The issue at dispute between the Applicant and Respondent is whether the as built travel distances, ranging from 53 to 56 m on floors two to five, in a structure considered to have interconnected floor space due to the atrium, provides sufficiency of compliance with Sentence 3.2.8.4.(4) and Clause 3.4.2.5.(1)(b). This latter provision of the OBC stipulates a maximum travel distance of 40 m to an exit from a floor area that is required to have more than one exit. At issue therefore, are the travel distances that exceed the 40 m maximum by as much as thirty to forty per cent longer than allowed by the OBC.

4. ***Provisions of the Ontario Building Code***

Sentence 3.2.8.4.(4) Exits

(4) Except where exits serving the floor area are at ground level, the increased travel distance to exits permitted by Clause 3.4.2.5.(1)(c) shall not apply to a floor area within an interconnected floor space.

Sentence 3.4.2.5.(1) Location of Exits

(1) Except as permitted by Sentences (2), (3) and 3.3.2.4.(6), if more than one exit is required from a floor area, the exits shall be located so that the travel distance to at least one exit shall be not more than

(a) 25 m (82 ft) in a high hazard industrial occupancy,
(b) 40 m (131 ft 3 in) in a business and personal services occupancy,
(c) 45 m (147 ft 8 in) in a floor area that contains an occupancy other than a high hazard industrial occupancy, provided it is sprinklered,
(d) 105 m (344 ft 6 in) in any floor area, served by a public corridor, in which rooms and suites are not separated from the remainder of the floor area by a fire separation, provided
(i) the public corridor is not less than 9 m (29 ft 6 in) wide,
(ii) the ceiling height in the public corridor is not less than 4 m (13 ft 1 in) above all floor surfaces,
(iii) the building is sprinklered, and
(iv) not more than one half of the required egress doorways from a room or suite open into the public corridor if the room or suite is required to have more than one egress doorway,
(e) except as permitted by Sentence (5), 60 m (196 ft 10 in) in any storage garage that conforms to the requirements of Article 3.2.2.83., and
(f) 30 m (98 ft 5 in) in any floor area other than those referred to in Clauses (a) to (e).

5. ***Applicant's Position***

The Applicant submitted that while the second to fifth floor travel distances do exceed the 40 m maximum allowed in the OBC the actual exit time from the floor areas is not increased and therefore does not constitute a risk to life safety. He indicated that his primary argument to support this assertion and thereby demonstrate sufficiency of compliance is based on a timed exit analysis. The Applicant provided a description of the timed egress analysis employed.

The timed exit analysis was based on the methodology set out in the SFPE Handbook of Fire Protection Engineering, 2nd Edition. The analysis was done for all floors in the OMAFRA building in which the travel distance exceeds 40 m. The study measured how long it would take

to get through a door at the given width, how long it would take to get to that door, etc. A comparative analysis was also performed for a hypothetical floor area that complies with the OBC.

The Applicant indicated that the range of times he calculated it would take to travel across the floor area and to enter the exit stair enclosure was 1.68 minutes on the south wing of the fifth floor which has the lowest occupant load at 198 persons of the disputed floors areas to 2.63 minutes for the second floor of the north wing which has the highest occupant load of 422. The Applicant noted that the queue that would form at the exit door would be the bottleneck in the exit path. The time that it would take to get to the exit door is minor compared to the time it would take to get through the door itself. However, even though the travel distance exceeds the 40 m, since they have provided more than the required exits, this means that the occupants have more exit options and the queues at each door would be less, thereby facilitating quicker exiting.

In comparison, he noted that the travel time for a Code complying structure, in which exit stairs are provided based on the exit requirements of calculated occupant load, is 3.23 minutes. The Applicant argued that this higher time results from the larger and longer queues at these exits because there are less of them than in the OMAFRA building. He noted that even the slowest exit times in the OMAFRA building are significantly lower than that permitted by the OBC.

The Applicant concluded by stating that since the travel distance times are lower than those permitted by the OBC that sufficiency of compliance has been achieved and that the subject building does not pose an increased life safety risk.

6. ***Respondent's Position***

The Respondent indicated that his position was clear. The Code requires that the travel distance in the subject building be limited to 40 m. He noted that in all disputed floor areas the travel distance is exceeded by at least thirty per cent and in at least one case it is forty per cent over the 40 m maximum distance allowed.

The Respondent also indicated that there are no specific provisions in the OBC that would allow him to accept a timed exit analysis or other such studies as an equivalent under the Code to the permitted 40 m travel distance. He noted that they do not have strong objections to the Applicant's arguments.

7. ***Commission Ruling***

It is the decision of the Building Code Commission that the travel distance on the second to fifth floors ranging from 53 to 56 m, in a structure with interconnecting floor space due to the full height atrium provides sufficiency of compliance with Sentence 3.2.8.4.(4) and Clause 3.2.8.5.(1)(b) of the Ontario Building Code at the OMAFRA head office building, 95 Stone Road West, Guelph, Ontario.

8. ***Reasons***

(i) Excess stair capacity provides sufficiency of compliance.

(ii) Timed exit analysis shows time taken for all occupants to exit is no longer and is in fact less than that for a Code complying building.

RULING

1. **The Applicant**

   Mr. Rob Adamson, Architect, has applied for a building permit under the *Building Code Act, 1992* to construct a building and garden supply retail warehouse outlet known as Revy Home and Garden at 2933 Eglinton Avenue West, Mississauga, Ontario.

2. **Description of Construction**

   The Applicant is proposing to construct a new, single storey, Group E - mercantile (retail warehouse) occupancy, with a building area of 10,417 m^2. The building will be of noncombustible construction and will be equipped with an electronically supervised sprinkler system, fire alarm system and standpipe and hose system.

   The Applicant is also proposing to construct a 2,252 m^2 outdoor garden centre abutting the west exterior wall of the main building. The construction in dispute involves the approximately 613 m^2 of the garden centre which is planned as an area (16.8 m by 36.5 m) to be covered by a

temporary roof structure to provide weather protection for occupants as well as the horticultural products. The covering material is a clear flexible vinyl fabric called Frosty 3000 manufactured by Vanagard. It conforms to CAN/ULC S109-M87 "Standard for Flame Tests of Flame-Resistant Fabrics and Films". The fabric is supported by an aluminium frame. The frame would be built at a height of 4.87 m adjacent to the building and 3.35 m at the far end above the finished floor. The Applicant is also proposing to install on the aluminium frame just below the fabric a dry-pipe sprinkler system equipped with close spaced (10 by 10 ft), 165 degree quick response sprinkler heads.

The exterior wall of the store is composed of metal panels insulated with noncombustible mineral wool mounted on top of concrete block to a datum of 8 ft A.F.F. There is 8 ft of metal clad siding with no fire resistance rating above the block that is exposed to the covered area. There are several windows and doors between the building and garden centre. The garden centre is open on the three sides which do not abut the building. Required exiting from the store does not pass through the garden centre.

3. **Dispute**

The issue at dispute between the Applicant and Respondent is whether the proposed vinyl fabric roof on an aluminium frame to serve as a cover for the garden centre at the Revy Home and Garden warehouse store provides sufficiency of compliance with Article 3.1.5.22. of the Ontario Building Code. Specifically, at issue is whether the covered area of the garden centre, at approximately six per cent of the size of the entire building, can be considered as a canopy. If it is deemed not to be a canopy then the exemption provided for combustible canopies attached to noncombustible buildings found in Sentence 3.1.5.22.(1) may not apply to the Revy Home and Garden, thus making the noncombustible requirements of 3.2.2.57. applicable. If not considered a canopy, the Applicant is offering sprinkler protection as a compensating measure to achieve sufficiency of compliance.

If the covering is considered as a tent as per Subsection 3.13.1. then many Code requirements do not apply (although the fabric must still meet the CAN/ULC S-109-M87 standard). As a trade off, however, the Code requires that tents must maintain a spatial separation of 3 m from any building, which is not provided between the covered area and the subject building.

4. **Provisions of the Ontario Building Code**

Article 3.1.5.22. Canopies Having Combustible Elements

(1) Exterior canopies having combustible fabrics or films are permitted on a building required to be of noncombustible construction provided the fabrics and films conform to CAN/ULC-S109-M, "Standard for Flame Tests of Flame-Resistant Fabrics and Films".

(2) Except as permitted in Sentence (3), exterior marquees, not greater than 7.5 m (24 ft 7 in) from ground level to the top of the marquee, having combustible elements other than fabrics or films conforming to Sentence (1), are permitted on a building required to be of noncombustible construction, provided every opening in the exposed wall of the building above the marquee is protected with wired glass in accordance with the Supplementary Guidelines where these openings are within

(a) 4.5 m (14 ft 9 in) horizontally of the marquee, and
(b) 9 m (29 ft 6 in) vertically above the marquee

(3) The protection required by Sentence (2) is permitted to be waived if the building is sprinklered.

5. **Applicant's Position**

The Applicant submitted that even though the covered area is certainly large it can still be considered as a canopy with an occupancy beneath it. As he indicated, there are no maximum dimensions or areas set out in the Code for canopies. As a result, he argued that the exemption for combustible canopies found in Sentence 3.1.5.22.(1) would apply to the subject building. This exemption, he noted, applies to fabrics that meet the CAN/ULC S109-M87 standard, which is the case with the intended fabric. As a canopy with an occupancy below it, NFPA 13 sprinkler protection would be required. Since he is proposing a sprinkler system, it is his view that, as a canopy it would meet the life safety standards intended in Sentence 3.1.5.22.(1).

Alternatively, if considered as a tent, the Applicant argued that the proposed covering would also meet the safety standards found in Subsection 3.13.1. As he noted, a sprinkler system is not required for a tent, therefore, in his opinion, it would be a suitable compensating measure for the 3 m set back required under Sentence 3.13.1.4.(2).

The Applicant then argued that regardless of what the covering is considered to be, it will be a safe area. The primary safety feature, he indicated, was the sprinkler system. He noted that the 75 degree, close spaced, sprinkler heads would provide quick actuation in the event of a fire. He indicated that the material to be used does not soften until approximately double the temperature

at which the sprinklers activate. This fast response would control any fire that occurred in the garden centre and would offer exposure protection to the windows and doors in the store. The Applicant further noted that the fabric has a flame spread rating of less than 25 and a low smoke development classification.

In terms of exiting from the garden centre, the Applicant recognized that there may some debate about whether 30 or 45 m would be required. Nevertheless, since the covered area is served by two exit doors, one on the south side and the other into the building at the east, the actual travel distance from anywhere in the garden centre is less than 15 m. The Applicant also pointed out that the store, with exits placed every 60 m, does not rely on exiting through the garden centre.

Other safety features include fire department access to the south and west sides of the garden centre. As well, a fire hydrant is located within 445 and 85 m of the south and north ends respectively of the garden centre. Finally, the Applicant noted that the fire alarm system from the store, including manual pull stations and audible devices, would be extended into the garden centre, as would the emergency lighting.

For the above reasons, whether the covered area is considered as a canopy, tent or an addition to the building, the Applicant concluded by arguing that the safety features, especially the sprinkler system, will mean that the subject garden centre covering will meet the intended level of life safety required in the OBC.

6. **Respondent's Position**

The Respondent indicated that, in his view, he does not consider the proposed garden centre as a canopy to the main building. He submitted that, at roughly 613 m^2, it is properly considered as an addition to the main building. Consequently, he argued that the exception allowed in 3.1.5.22.(1) is not applicable and that the noncombustible requirements of 3.2.2.57. must be met. The proposed fabric, the Respondent felt, as a combustible material does not meet the Ontario Building Code.

Further, the Respondent expressed concern about the metal clad portion of the abutting wall of the building that faces the covered area. He noted that previous BCC rulings relied upon fire separations with at least a 2 hour fire resistance rating. This level of separation is not present in the subject building.

Lastly, he indicated that he would feel more comfortable if a 3 m separation between the building and the covered area was imposed. In his opinion, this would compensate for the zero fire resistance rating in the higher portion of the abutting wall.

7. **Commission Ruling**

It is the decision of the Building Code Commission that the use of a vinyl fabric roof as a cover for the Garden Centre provides sufficiency of compliance with Sentence 3.1.5.22(1) of the Ontario Building Code at the Revy Home and Garden Centre, 2933 Eglinton Avenue West, Mississauga, Ontario provided that the material cover to be used is Vanagard Frosty 3000-14 and that closely spaced sprinklers be installed at the exit to the existing structure.

8. **Reasons**

(i) The sprinkler system in the tent subject to an adequate design plus the addition of closely spaced sprinklers at the exit to the existing structure provides sufficiency of compliance.

(ii) The Vanagard Frosty 3000-14 meets the CAN/ULC S109-M87 standard and complies with 3.1.5.22.(1).

RULING

1. **The Applicant**

   Ms. Liz Rozenberg, Corporate Director, Facilities, has applied for a building permit under the *Building Code Act, 1992* to construct several additions to the Lakeridge Health Corporation at 1 Hospital Court, Oshawa, Ontario.

2. **Description of Construction**

   The Lakeridge Health Corporation is an existing, nine storey hospital facility that is equipped with a fire alarm system and a standpipe and hose system, but not a full sprinkler system. (A full sprinkler system will be phased in over several years.) The Applicant is proposing to construct

one new wing and two new infill additions onto the subject building. Two of the three additions have disputed areas of construction. These two additions are described below.

The North Infill is an addition intended to fill the space currently existing between the two storey D-Wing to the east, the six storey A-Wing to the south and the nine storey F-Wing to the west. It is proposed as a 1,000 m^2 in building area, two storey high open space that is to contain Group A - Division 2 (food court with subsidiary kitchen) assembly and Group E (retail kiosks) mercantile occupancies. The North Infill will be provided with an electronically supervised sprinkler system built in accordance with NFPA 13 and will be separated from the surrounding non-sprinklered floor areas by a one hour fire separation from the adjoining office occupancies and by a two hour fire separation from the B2 occupancies. The floor will have a minimum fire-resistance rating of two hours, the roof, on the other hand, comprised of glass and steel is proposed by the Applicant to be unrated. The existing roofs on the D, A and F wings have a fire-resistance rating of one hour.

The new North Wing, located north of the existing G-Wing and north west of the existing F-Wing, is two storey (plus two levels below grade), L-shaped addition that is to provide further Group B - Division 2 (hospital) care occupancy space to the existing facility. The North Wing will also be fully sprinklered.

In the southerly portion of the eastern most face of this addition is a small area that links the new North Wing to the new North Infill and to an exit stairwell serving all floors of the existing F-Wing, as well as providing an exit to the exterior. This linking area ("the Link") is to become a major pedestrian circulation route for the expanded hospital, including the multi-layered parking facility to the north. In fact, the North Wing has three sets of double doors (one pair swinging east to west and two pairs swinging north to south) that lead into the Link, two double doors connect the North Infill and the Link, a single door leads from the F-Wing exit stairwell into the Link, and a single double provides access from the Link to the exterior. Of these doors, the two north to south double doors leading from the North Wing to the Link and both double doors leading from the North Infill to the Link are to be equipped with hold-open devices. The other doors served by the Link will not have hold-open devices. The Link will be pressurized, sprinklered and will have a one hour fire separation from adjacent occupancies.

3. **Dispute**

There are two issues at dispute between the Applicant and Respondent. The first is whether the sprinkler system proposed to be installed throughout the North Infill compensates for the unrated

roof assembly proposed for this addition thereby providing sufficiency of compliance with Article 3.2.2.17. of the Ontario Building Code. This provision permits a sprinkler to be installed in lieu of a rated roof assembly provided, among other things, that "the building is sprinklered". If the building in this case is construed to mean the entire hospital structure, which is not fully sprinklered, then the unrated roof may not be allowed. Article 3.2.2.38. which governs the construction of the new additions to the hospital, however, does not specify a rating for the roof assembly.

The second dispute involves the proposed installation of hold-open devices on doors between the North Wing, the North Infill and the Link and whether this complies with Article 3.1.8.12. of the OBC. Article 3.1.8.12. stipulates that hold-open devices can be installed on doors in a fire separation except if the doors are considered as a required exit doors in a building greater than three storeys. Since the two storey North Infill and the two storey North Wing were built without firewalls between the adjoining wings they are considered part of the larger nine storey building. The issue, therefore, revolves around whether the doors leading into the Link from the North Infill, the North Wing and the F-Wing exit stairwell are considered required exit doors.

4. **Provisions of the Ontario Building Code**

Article 3.2.2.17. Sprinklers in Lieu of Roof Rating

(1) The requirements in Articles 3.2.2.20. To 3.2.2.83. For roof assemblies to have a fire-resistance rating are permitted to be waived provided

(a) the building is sprinklered,
(b) the sprinkler system in Clause (a) is electrically supervised in conformance with Sentence 3.2.4.9.(2) and
(c) the operation of the sprinkler system in Clause (a) will cause a signal to be transmitted to the fire department in conformance with Sentence 3.2.4.7.(4).

Article 3.1.8.12. Hold-Open Devices

(2) Except as required by Sentences (3), (5), (6) and (7), a hold-open device permitted by Sentence (1) shall be designed to release by a signal from (a) an automatic sprinkler system,
(b) a heat-actuated device,
(c) fusible link, or

(d) a smoke detector located as described in Appendix B of NFPA 80, "Standard for Fire Doors and Fire Windows".

(3) Except as required by Sentences (4), (5), (6) and (7), a hold-open device permitted by Sentence (1) shall be designed to release upon a signal from a smoke detector located as described in Appendix B of NFPA 80, "Standard for Fire Doors and Fire Windows", if used on
(a) an exit door,
(b) a door opening into a public corridor,
(c) an egress door referred to in Sentence 3.4.2.4.(2),
(d) a door serving
(i) an assembly occupancy,
(ii) a care or detention occupancy, or
(iii) a residential occupancy, or
(e) a door required to function as part of a smoke control system.

(4) Except as required by Sentence (5), (6) and (7), a hold-open device permitted by Sentence (1) shall be designed to release upon a signal from the building fire alarm system if a fire alarm system is provided, except that this requirement does not apply to
(a) a hold-open device on a door located between a corridor used by the public and an adjacent sleeping room in a hospital or nursing home, or
(b) a hold-open device that is designed to release by a heat-actuated device or a fusible link in conformance with Sentence (2).

(5) Sentences (2) and (3) do not apply in a hospital or nursing home to
(a) a door located between a corridor used by the public and an adjacent sleeping room, or
(b) paired doors described in Sentence 3.3.3.3.(4).

(6) A hold-open device on a door in Clause (5)(a) shall be designed to release the door upon a signal from
(a) a smoke detector as required by Sentence 3.2.4.11.(1) for sleeping rooms in Group B occupancies, and
(b) the fire alarm system when an alert signal is initiated within the same fire compartment in Sentence 3.3.3.5.(2).

(7) A hold-open device on a door in Clause (5)(b) shall be designed to release the door upon a signal from the fire alarm system when an alert signal is initiated within the same fire compartment in Sentence 3.3.3.5.(2).

(8) A rolling steel fire door installed as a closure in a fire separation shall be equipped with a hold-open device designed to release the shutter as described in Sentence (2).

5. **Applicant's Position**

Regarding the issue of the unrated roof assembly in the North Infill, the Applicant submitted that proposed electronically supervised sprinkler system built to NFPA 13 standards which covers the entire 1,000 m^2 North Infill area provides sufficiency of compliance with Article 3.2.2.17. of the OBC. He argued that the sprinkler system comprises part of a complete package of protection including suppression and compartmentation which has been provided for the North Infill. As he noted, not only is the North Infill separated from the adjoining occupancies by one and in some cases two hour fire separations, but all connecting spaces have been constructed as pressurized vestibules with one or two hour rated construction. Moreover, the former windows of the F-Wing facing the North Infill have been replaced with wired or tempered glass in metal frames and will be provided with window sprinklers on both sides of the wall. As well, the floors will have a two hour fire-resistance rating.

In conjunction to these compartmentation measures, the roof will be protected by the proposed sprinkler system, which will also serve to protect the space itself, including occupants. In the case of the North Infill, in which the second storey roof level is lower than the surrounding portions of the building, the sprinkler system will also prevent a roof-to-wall fire exposure, the Applicant stated. He noted that a previous BCC decision upheld this argument. The Applicant also argued that sprinkler systems in general have an excellent record of protecting life and property. Moreover, he indicated that it is a well accepted principal in the OBC that certain fire-resistance ratings can be waived if a compensating sprinkler system is installed. As he noted Article 3.2.2.17., "Sprinklers in Lieu of Roof Rating", allows exactly this trade off if the various conditions found in that provision are met.

The Applicant argued that they meet all the conditions of Article 3.2.2.17., except for Clause (1)(a) which deals specifically with requiring the entire building to be sprinklered. Nevertheless, he contended that all of the above measures combined mean that the North Infill would be more than adequately protected. This holds true, the Applicant argued, if a fire were to originate from inside the North Infill or elsewhere in the hospital because the separations would offer protection in both directions. The intent of the Code, he explained, was to require either a one hour fire-resistance rating or sprinkler system for roof assemblies. This building proposes to use both protection measures in different areas to provide complete protection. In their view, sprinkler

protection throughout the entire building is not the only way to meet the intended safety requirements of the Code. To support his position, the Applicant noted that Article 3.2.2.38. does not even specify a rating for roof assemblies, but it does require that the new addition be fully sprinklered. Essentially, he argued that this allows flexibility to use either protection method to achieve roof assembly safety.

On the issue of the hold-open devices, the Applicant acknowledged that the Code does not allow such items on the doors discharging into the Link from the North Infill and the North Wing because they are considered a part of the high-rise component of the hospital and because he believes they are required exit doors. However, he argued that the installation of hold-open devices will ensure that a high level of safety will be maintained. As he pointed out, since the Link area is designed as a high pedestrian traffic zone and with doors that must be constantly opened there will be great temptation to wedge the subject doors open. This would completely defeat the fire separation and pressurization of the Link in the event of a fire. In contrast, hold-open devices, the Applicant stated, would provide the many pedestrian users with the convenience of doors that are nearly always open but would close upon activation of the fire alarm system, thereby maintaining the integrity of the designed fire safety measures.

The Applicant also addressed the egress issue from the F-Wing's exit stairwell which now discharges into the Link before gaining access to the exterior. He noted that there are 13 doors serving the Link, 11 discharge into the Link (in terms of path of exit travel) and two discharge to the exterior. Of the 11 doors, four leading from the North Infill and four leading from the North Wing are proposed to be equipped with hold-open devices. The door from the F-Wing exit stairwell will not have a hold-open device. All eight of the hold-open doors will automatically shut when the fire alarm system is activated, thereby preserving the required fire separation surrounding the exit route and making the Link area an exit lobby in conformance with Article 3.4.4.2., the Applicant argued.

Lastly, the Applicant noted that smoke detectors are proposed inside the Link area adjacent to the eight doors with hold-open devices. Additional smoke detectors will be located on the North Infill and North Wing side of the subject doors. These smoke detectors will be tied into the fire alarm system so that their activation will also cause the hold-open devices to close the doors. In his view, the hold-open devices, by automatically closing in an emergency and by preventing doors wedged open, provide sufficiency of compliance with the life safety intended by the OBC and in fact may be safer.

6. **Respondent's Position**

Concerning the unrated North Infill roof assembly, the Respondent submitted that her interpretation of Article 3.2.2.17. of the Code is that it allows the required roof rating to be substituted with sprinklers on certain conditions described in this provision, including that the building is fully sprinklered. As she noted, the remainder of the existing nine storey building is not sprinklered, meaning that the condition set out in Clause 3.2.2.17.(1)(a) is not met. As a result, she argued that the roof assembly of the North Infill was required to be fire rated.

The Respondent argued that the Code was clear regarding the issue of the proposed hold-open devices. Again, she indicated that the North Infill, although only two storeys itself, was considered as part of the overall nine storey hospital building as is the North Wing. She also noted that doors leading from the North Infill and North Wing to the Link were, in her opinion, considered required exit doors. These factors, she argued, meant that the hold-open devices on the four North Infill-to-Link doors and the four North Wing-to-Link do not comply with Sentence 3.1.8.12.(1) and were therefore not permitted.

She also expressed concern about the F-Wing exit stair exiting through the Link that has many doors discharging into it, most of which are equipped with hold-open devices. In her view, this compromises the safety the occupants of the F-Wing and their ability to exit safely in an emergency situation.

For these reasons, the Respondent indicated that the unrated roof assembly in the North Infill area and the hold-open devices proposed for the subject doors do not provide sufficiency of compliance with Articles 3.2.2.17. and 3.1.8.12. respectively of the OBC.

7. **Commission Ruling**

It is the decision of the Building Code Commission that the proposed additions to the Lakeridge Health Corporation Oshawa provides sufficiency of compliance with Articles 3.2.2.17 and 3.1.8.12 of the Ontario Building Code.

8. **Reasons**

i) Articles 2.1.1.7. and 11.3.2.1. of the Building Code indicate that the requirements of 3.2.2.38. apply only to the new North Infill and the new North Wing additions. The sprinklering of these portions of the building permit the roof assemblies in these areas to be unprotected.

ii) The use of magnetic hold-open devices on the main floor link locations between the new North Infill and new North Wing are permitted as it has been determined that these are access to exits from the floor area.

iii) In addition, the Link as an interconnecting vestibule is sprinklered, and pressurized to limit smoke movement in the event of fire.

iv) The installation of smoke detectors on either side of the access to exit doors at the Link area from the adjacent floor areas add to the level of safety by closing in event of detection of smoke.

Mr. Kirk Carter
Plumbing Inspector
City of Oshawa
The Respondent

RULING

1. **The Applicant**

   Mr. Matthew Maciejowski, Senior Project Manager, has received an order under the Building Code Act, 1992 to comply with Article 7.2.5.1. of the Ontario Building Code at the Canadian Tire outlet, 441 Gibb Street, Oshawa, Ontario.

2. **Description of Construction**

   The Applicant is currently constructing a one storey, Group E - mercantile (retail) occupancy, with a building area of 8,064 m^2. The structure is constructed of noncombustible construction and is to be equipped with a sprinkler system and a fire alarm system.

   The construction in dispute involves certain aspects of the plumbing system and the internal rain water leaders, specifically the asbestos-cement pipe fittings manufactured by Logard Inc.

3. **Dispute**

The issue at dispute between the Applicant and Respondent is whether the subject asbestos-cement pipe fittings, as installed, in the Canadian Tire store comply with Article 7.2.5.1. of the Ontario Building Code. This provision indicates that all asbestos-cement pipe fittings used in a building above ground shall conform to one of two standards, one of which is the CSA standard B127.1, "Components for Use in Asbestos-Cement Drain, Waste and Vent Systems". While the subject fittings have been used, and continue to be used, extensively for construction in Ontario, they are currently not approved by CSA in terms of conformance with their B127.1 standard, specifically the bending test portion of that standard. The product is currently being evaluated by CSA, however, the CSA standard itself is in the process of being amended.

4. **Provisions of the Ontario Building Code**

Article 7.2.5.1. Asbestos-Cement Drainage Pipe and Fittings

(1) Except as provided in Sentence (2), asbestos-cement pipe and its fittings for use in a drain, waste or vent system shall conform to

(a) CAN/CGSB-34.22, "Pipe, Asbestos-Cement, Drain", or
(b) CSA B127.1, "Components for Use in Asbestos Cement Drain, Waste and Vent Systems".

(2) Asbestos-cement pipe and fittings used underground either outside a building or under a building shall conform to Sentence (1) or to

(a) CAN/CGSB-34.9, "Pipe, Asbestos-Cement, Sewer",
(b) CAN/CGSB-34.23, "Pipe, Asbestos-Cement, Sewer, House Connection", or
(c) CSA B127.2, "Components for Use in Asbestos-Cement Building Sewer Systems".

5. **Applicant's Position**

The Applicant submitted that while his product does not currently meet CSA standard, he indicated that he has assurances from CSA that it will be able to meet the standard in the near future. Further, he argued that the Logard asbestos-cement pipe fittings have been used for construction in Ontario for many years and continue to be widely installed. The Applicant noted that the bending test portion of the CSA B127.1 standard was the specific issue at dispute regarding the asbestos-cement fittings.

The Applicant provided some background regarding asbestos-cement pipe fittings and the CSA standard. In their view, the problem began as far back as 1977 when the Ontario Plumbing Code

first referenced the CSA B127.1 standard. That standard, they noted, only provided tests for the pipe and not the fittings. Since the fittings were not subject to specific testing they were judged on their performance, which he argued was excellent.

This was the case until 1984 when the Ontario Plumbing Code was updated and amended with the approval of O. Reg. 815/84. Among other things, this regulation amended the provision of the Plumbing Code (which eventually became OBC Article 7.2.5.1) that dealt with testing standards for asbestos-cement pipes. This provision was changed to include the words "and its fittings", thereby requiring that not only the pipe, but also the fittings were to conform to CSA B127.1.

The difficulty with this however, the Applicant noted, was that at the time the CSA standard had not in fact been changed to include tests for asbestos-cement fittings. So in essence manufacturers of asbestos-cement fittings were put in the conundrum of having no standard for the fittings to conform to even though conformance was required by the OBC. It was only in 1990 that CSA changed its B127.1 standard to actually provide tests for fittings, including a bend test. This test, however, is widely regarded as not an effective measure of the product, he argued. It is for this reason that the current CSA B127.1 is being revised.

Lastly, as a result of this rather unconventional situation, the Applicant stated that the manufacturers, designers, contractors and building officials, etc. have had to take a practical approach to the use of asbestos-cement fittings. Part of the approach, he argued, was that municipalities can approve the use of his product as an equivalent under Section 2.7. of the OBC. He noted that all municipalities, with the exception of Oshawa, either have no problems with the subject fittings, or are willing to accept them as an equivalent, and are prepared to wait until the new standard is approved and the product is tested to that more appropriate standard.

6. **Respondent's Position**

The Respondent submitted that the Logard asbestos-cement pipe fitting does not currently meet the CSA B127.1 standard and should therefore not be used in the construction of the subject building. He acknowledged that while other municipalities may be willing to accept the product as an equivalent, Oshawa is not. He indicated that they have had at least two recent experiences of asbestos-cement pipe fitting failures. Even though the failed fittings were not Logard products, the Respondent argued that it is an industry-wide problem.

The Respondent explained that his specific concern with the fittings is that their design does not provide for a smooth bore radius sweep at the joints. Because it is not smooth where the fitting and the pipe join, as liquid passes over this interior lip, friction results. This friction causes undue pressure on the fittings which, due to the nature of their asbestos-cement material, is hardly flexible and will, in extreme cases, cause failure. To compensate for this lack of smoothness inside the fittings extensive, and in the Respondent's view excessive, epoxy caulking must be used on the pipe interior.

The Respondent indicated that when, or if, CSA approval is forthcoming, it should cover this product for use as rain water leaders for storm drainage only. This is due to the fact that rain water does not provide the same extreme fluctuations in terms of hydrostatic pressure as occurs in a sanitary sewage system.

Finally, because the subject product does not currently meet the CSA standard referenced in Article 7.2.5.1., he felt that their use did not comply with the OBC and consequently an order to remove the fittings was issued. The Respondent indicated, however, that there is another standard found in OBC 7.2.5.1., the CAN/CGSB-34.22, to which asbestos-cement products can conform. He allowed that if this standard was relevant, i.e. provides appropriate tests for fittings, and if the Applicant can demonstrate compliance, then he would not object to the use of the subject Logard asbestos-cement fittings in the Canadian Tire Store.

7. **Commission Ruling**

It is the decision of the Building Code Commission that the fabricated asbestos cement pipe fittings do not provide sufficiency of compliance with CSA B.127.1 referenced in 7.2.5.1 of the Ontario Building Code.

8. **Reasons**

i) The CSA B.127.1 standard is presently under review by the technical committee to address certification of fittings.

ii) There is a CAN/CGSB-34.22 standard referenced in Article 7.2.5.1 of the Building Code. The Applicant has stated they will provide evidence to the municipality on conformance with that standard.

RULING

1. **The Applicant**

   Mr. Mark Keighley, Burlington, Ontario, has applied for a building permit under the *Building Code Act, 1992* to install a Class 2 (leaching pit) sewage system at his seasonal residence located on an island at Lot 24, Concession 8, Plan 537, Sub Lot 25, Township of Guilford, Haliburton County, Ontario.

2. **Description of Construction**

   The Applicant has applied for a building permit for a recently constructed Class 2, leaching pit sewage system at his single, detached, two storey, Group C- seasonal residential dwelling located on Redstone Lake. The building is described as having two bedrooms, 4.5 fixture units and a total finished floor area of 121 m^2. The calculated daily design sewage flow rate is 1,100 litres per day. The Applicants are not contemplating any renovations to the existing structure.

The construction in dispute involves the Applicant's as constructed leaching pit that serves the grey water from the subject dwelling by means of gravity disposal. The cottage, however, is also equipped with a pressurized water system that draws surface water from the nearby lake. (The single toilet in the cottage is a Sun-Mar composting unit. The Applicant has agreed to disconnect the overflow pipe from the unit which is currently connected to the leaching pit.)

The Class 2 system, as installed, consists of a 100 mm diameter pipe running from the dwelling to the pit, approximately 8 m away. The pit is described as a 1 m deep circular hole with a diameter of approximately 2.7 m, for a total volume of roughly 2.7 m^2. A 1 m by 2.5 m rectangular box of concrete block stand in middle of the pit extending slightly higher than the surrounding grade level. The outside of the concrete block is covered in chicken wire to prevent stones from entering the pit. Stones surrounding the concrete block box fill the pit. The pit is covered by plywood, while the surrounding stones are covered with earth that is graded to slope away from the concrete block box.

The site is one of a number of properties on the subject island. The property has a gradual slope towards the lake that varies between five to fifteen per cent and is covered with immature hardwood trees. The soil is described as sandy loam to at least a depth of 1.5 m and has an estimated percolation time of 5 to ten minutes per centimetre. The cottage is situated 50 m from the lake, whereas the leaching pit is set back 59 m from the lake.

3. **Dispute**

The issue at dispute between the Applicant and Respondent is whether the already constructed Class 2 leaching pit provides sufficiency of compliance with Sentence 8.4.1.2.(2) of the Ontario Building Code. This provision prohibits the use of a Class 2 sewage system in conjunction with a pressurized water system. The Applicant's water and sewage systems clearly combine these two methods of drawing and distributing water and disposing of effluent.

4. **Provisions of the Ontario Building Code**

Sentence 8.4.1.2.(2) Application

(2) A Class 2 sewage system shall not be constructed where there is a supply of pressurized water.

5. **Applicant's Position**

The Applicant submitted that while his Class 2 system does not comply with Sentence 8.4.1.2.(2) his sewage system does in fact work well and has done so with previous leaching pits. He argued that the amount of grey water produced by the few (mostly only two) occupants who are there on a seasonal only basis is readily handled by the leaching pit as constructed. He also noted that by disconnecting the overflow pipe from the Sun Mar composting toilet the more hazardous wastes are eliminated from entering the pit.

The Applicant also argued that to install a Class 4 or 5 system would be a heavy financial burden. Moreover, due to the fact that the subject property is located on an island would likely mean that any Class 4 or 5 system would be difficult to service in the future.

Lastly, the Applicant argued that the OBC, as written, does not offer enough flexibility to consider servicing a property such as his that is infrequently used, but is equipped with pressurized water yet produces little effluent. He indicated, however, that it was his understanding that the Ministry of Municipal Affairs and Housing was reviewing this provision with the intention of possibly providing greater flexibility under certain conditions. The Applicant asked that the Commission consider this possible Code amendment when deliberating on his appeal.

6. **Respondent's Position**

The Respondent submitted that Sentence 8.4.1.2.(2) prohibits the use of a Class 2 sewage system in combination with a pressurized water system. Although he sympathized with the Applicants' position, the Code, he noted was quite clear on this restriction. He indicated that he appreciated the Applicant's willingness to disconnect the composting toilet from the leaching pit sewage pipe. He also stated that he agreed with the Applicant the subject dwelling will not yield considerable effluent. Nevertheless, because the prohibition in the Code regarding combining a pressurized water system with a leaching pit is absolute, the Respondent indicated that he had no authority to accept the Applicant's proposal.

Lastly, the Respondent indicated that he felt he had no authority to accept the Applicants' proposal.

7. **Commission Ruling**

It is the decision of the Building Code Commission that a Class 2 system meeting the requirements of 8.4.2.3. of the Building Code provides sufficiency of compliance with Article 8.4.1.2. with a supply of pressurized water.

8. **Reasons**

i) The number of plumbing fixtures is limited and the volume of grey water is estimated to be 600 litres/day or 60% of the total sanitary flow permitted under Article 8.4.2.2.

ii) The system is used only for the treatment and disposal of grey water and services a seasonal residence.

iii) Previous practices under the Environmental Protection Act limited the use of such systems with pressurized water supply to systems with limited number of fixtures, and a review of the Building Code is presently underway.

RULING

1. **The Applicant**

   Mrs. Virginia Hinckley, cottage owner, Melrose, Massachusetts, has received a building permit under the *Building Code Act, 1992* to install a Class 5 (holding tank) sewage system at her seasonal residence at Island 15A, Stoney Lake, Township of Burleigh, Peterborough County, Ontario.

2. **Description of Construction**

   The Applicants are proposing to install a new Class 5 sewage system at her 19th century single, detached, one and a half storey, Group C- seasonal residential dwelling located on Stoney Lake. The building is described as having six small bedrooms, 4.5 fixture units and a total finished floor area of 190 m^2. The calculated daily design sewage flow rate is 3,000 litres per day. The Applicants are not contemplating any renovations to the existing structure.

The construction in dispute involves the Applicants' proposal to revise the current building permit allowing the installation of a 21,000 litre holding tank and instead installing two fibreglass 5,000 litre holding tanks to serve the grey water from the subject dwelling by means of gravity disposal. The cottage is equipped with a pressurized water system and the 10,000 litre holding tank system is proposed as a replacement for the current Class 2 leaching pit used for grey water disposal. (The two toilets in the cottage are electric incinerator models and will not be connected to the proposed holding tanks.) The Applicants are also proposing to install the two holding tanks mostly below grade 5 m to the north of the cottage. They have begun discussions with a local sewage hauler to enter into a holding tank service agreement.

The site is a 1,538 m^2 island with a very gentle downward slope to the north and is covered with grass and some trees. The soil is described as sandy loam and has a variable depth from zero to 1.5 m in a few areas. Approximately thirty per cent of the island is exposed rock. The cottage is situation on the southern portion of the island, with the shoreline being 1.5 m to the south of the building and 16.8 m to the north. The percolation time of the native soil is 12 minutes per centimetre.

The subject dwelling is served by surface supply water pumped from the lake.

3. **Dispute**

The issue at dispute between the Applicants and Respondent is whether the proposed holding tanks, with a total capacity of 10,000 litres, provides sufficiency of compliance with Sentence 8.8.2.2.(1) of the Ontario Building Code. This provision requires that residential buildings served by holding tanks must have a seven day holding capacity based on the daily design sewage flow rate. When applying this provision to the subject building which has a daily design sewage flow calculated at 3,000 L/d times seven days in accordance with sentence 8.8.2.2.(1) means that a 21,000 litre holding tank is required.

4. **Provisions of the Ontario Building Code**

Article 8.8.1.2. Acceptable Installation

(1) A Class 5 sewage system may be installed in the following circumstances:

(a) where the proposed use of the sewage system is for a temporary operation, excluding seasonal recreational use, not exceeding 12 months in duration,

(b) to permit the extension of an existing single-family dwelling provided that

(i) the extension will not increase the wastewater load, and

(ii) the building is already served by a Class 5 sewage system,

(c) to remedy an unsafe sewage system where the remediation of the unsafe condition by the installation of a Class 4 sewage system is impracticable,

(d) to upgrade a sewage system on an existing lot or parcel of land, where upgrading through the use of a Class 4 sewage system is not possible due to lot size or clearance limitations, or

(e) as an interim measure for a lot or parcel of land until municipal sewers are available, provided that the municipality undertakes to ensure the continued operation of an approved hauled sewage system until the municipal sewers are available.

(2) Where a Class 5 sewage system is installed, a written agreement for the disposal of sanitary sewage from the sewage system shall be entered into with a hauled sewage system operator.

Sentence 8.8.2.2. Sizing of Holding Tanks

(1) All holding tanks used in residential dwellings shall have a minimum 7 day holding capacity based on the total daily design sanitary sewage flow.

5. **Applicant's Position**

The Applicants submitted that the proposed 10,000 litre tank provides sufficiency of compliance with Sentence 8.8.2.2.(1) of the OBC. As they argued, the size of the proposed tank is more than adequate to serve the cottage and its current use. In describing the use of the cottage they indicated that it is not heated nor insulated and is therefore only occupied between late June and early September. They calculate that the cottage is only in use for 270 man days per year and that while it has six bedrooms they are never all in use, except for approximately six weekends during the summer.

The Applicants also argued based on a monitoring of usage that their cottage does not produce anywhere near the estimated 3,000 L/d of sewage flow. As they noted, they are continuing to use their electric incinerator toilets which means they would not contribute any sanitary waste to the holding tanks. Despite having a pressurized water system , the amount of grey water is also

limited because of their current practices of using water such as taking "navy showers", etc. The Applicants estimated, in fact, that their actual water usage is 4,200 litre per month.

Moreover, both the barge and truck belonging to the local sewage hauler are not large enough to pump out the required 21,000 litre tank, the Applicants noted. This would likely require two pump outs per year. As they noted, for this cost they could also get the smaller tanks pumped out twice a year, if in fact they were to reach capacity at all.

Regarding the issue of the placement of the holding tanks, they argued that the larger tank would cause certain problems. The size of the tank, for example would mean that it would either very difficult or very costly to install it below grade at all. Having the tank installed basically on grade would create other problems, such as requiring mechanical pumping of effluent to reach the top of the tank. As well, since the island is situated in the Trent-Severn waterway, for water control purposes the waterway operators sometimes increase the water level to levels higher than nature would create and this high water may cause exposure problems for an unprotected holding tank not submerged below grade. They also added that the larger tank would dominate the limited landscape of the island.

Due to the fact that the island is too small and has very little ground cover, installing a Class 4 system is impossible, the Applicants argued. For this reason they approached the Health Unit with a proposal to install a holding tank suitable to their needs. However, because of the number of bedrooms in their cottage they are required under OBC Table 8.2.1.3.A to provide an excessively large holding tank, they argued. This Table, they noted, does not provide any allowances for seasonal dwellings. It is not their intent to avoid compliance with the regulations but they are looking for a practical application of the rules that takes into consideration their difficulties.

6. **Respondent's Position**

The Respondent submitted that the Code requires that the holding tank for a six bedroom cottage is 21,000 litres based on a daily design sewage flow rate of 3,000 L/d. Although he sympathized with the Applicants' position, the Code, he noted was quite clear on the requirements for the subject holding tank. While he respected the Applicants' arguments regarding limited water usage, he indicated that he could not accept this as an alternative to the larger tank. The Respondent expressed concern that future users or owners of the cottage may have larger occupant loads at the cottage because of the number of bedrooms. For these reasons, he argued that the 21,000 litre holding tank was necessary.

Lastly, the Respondent indicated that he felt he had no authority to accept the Applicants' proposal.

7. **Commission Ruling**

It is the decision of the Building Code Commission that the proposed two 5,000 litre holding tanks to serve a cottage containing 6 bedrooms situated on a 1,538 m^2 island provides sufficiency of compliance with Article 8.8.1.2. of the Building Code provided; a) it serves as a grey water system or, b) the holding capacity is increased to three tanks and 15,000 litres to serve the complete sewage system.

8. **Reasons**

i) The toilets are presently electric and do not contribute to the sewage flow.

ii) Evidence presented indicate that monitored sewage flow is significantly below the daily design flow calculated in Table 8.2.1.3(a).

iii) The cottage is a seasonal occupancy and that only four bedrooms are functionally useable.

iv) The Code presently requires monitoring of levels and contracts for pumping.

RULING

1. **The Applicant**

   Mr. Robert Hicks, homeowner, Kingsville, Ontario, has applied for a building permit under the *Building Code Act, 1992* to install a new Class 4 sewage system at Part of Lot 18, Concession 6, Town of Essex, Essex County, Ontario.

2. **Description of Construction**

   The Applicant is proposing to install a new Class 4 sewage system to serve a single, detached Group C - residential dwelling. The proposed dwelling will contain three bedrooms, three bathrooms, have 28 fixture units, and a total finished floor area of 178 m^2. The calculated total daily design sewage flow rate will be 2,000 litres per day. The subject dwelling unit is currently under construction.

   The proposed new sewage system would consist of a 2,300 litres per day DF60FF Whitewater tertiary treatment unit connected directly to the residence that would transmit effluent to a free

access sand filter, which in turn would be connected to a Zabel A300 effluent filter. From there the sewage would flow to a single chamber pump chamber. The effluent would move through these components of the system by means of gravity disposal. From the pump chamber, however, it would be time dosed into the trenches of the disposal bed.

The raised disposal bed and surrounding mantle, set back 5 m from the dwelling, will have a total hydraulic footprint of 762 m^2 and will be constructed of imported sand with a percolation rate of approximately 8 minutes per centimetre set on scarified native clay. With a contact area of 762 m^2 and a daily flow rate of 2,000 L/d, the application, or loading, rate is calculated at roughly 2.6 litres/m^2/day. The proposed raised bed is to have an area of 271 m^2 (24.2 m by 11.2 m) and will be 600 mm in height. Using the T-time of 8 min/cm of the imported fill, the length of distribution pipe was calculated to be 30 m and will be laid out in two parallel 15 m trench runs set at depth of 300 mm above the native clay.

The trenches will be located 2 m apart on centre, while the 1:4 slope surrounding the raised bed will commence at distance of 1 m from all sides of the trenches. The chambers set in the trenches would consist of the pressurized distribution pipe resting on 18 mm to 60 mm washed stone. The trench chambers would be covered with a filter cloth. The surrounding mantle will have a one per cent slope from north to south and as a result it will be 3.1 m in width, except to the south of the raised bed where it will be at least 15 m. A driveway encircling the house and sewage system would act as a berm on the north and east side of the mantle.

The site is described as level and covered with trees and low ground cover. The native soil is ranges from 75 to 200 mm in depth. Beneath it is a deep layer of clay with a percolation rate of at least 125 minutes per centimetre, as confirmed by three test holes.

The subject dwelling is served by a well water system.

3. **Dispute**

The issue at dispute between the Applicant and Respondent is whether the proposed 600 mm raised leaching bed with absorption trenches having a vertical separation of only 300 mm above soil with a percolation rate of at least 125 minutes per centimetre complies with Clause 8.7.3.2.(2)(e) of the Ontario Building Code. This provision requires that the bottom of the trenches of a shallow buried trench leaching bed system must provide a vertical separation of 900 mm above rock or the high ground water table. It is silent, however, on whether this separation applies also between the bottom of a shallow buried trench and soil with a T-time of

more than 125 min/cm. Since the Applicant is proposing only a total of 600 mm of imported fill for the entire raised bed, the subject trenches, at 300 mm above the clay, would not appear to comply if a 900 mm vertical separation is required.

4. **Provisions of the Ontario Building Code**

Clause 8.7.3.2. Absorption Trenches

(2) Absorption trenches constructed as shallow buried trenches shall be

(e) at least 900 mm at all points on the bottom of the absorption trench above the high ground water table or rock, and

5. **Applicant's Position**

The Applicant submitted the proposed leaching bed with a 300 mm vertical separation complies with the construction requirements for absorption trenches as set out in OBC Sentence 8.7.3.2.(2). Clause 8.7.3.2.(2)(e), he argued, does not deal with vertical separation from soil, including that with a T-time of greater than 125 min/cm. The result is that this provision of the Code was not applicable to the proposed sewage system. As the Applicant noted, Sentence (1) of the same OBC Article in dispute clearly specifies that the vertical separation from the bottom of absorption trenches in a conventional Class 4 system (i.e. a non-shallow buried trench system) to soil with a particular T-time must be 900 mm. The fact that the Code is silent on the vertical separation from soil in a shallow buried trench system, the Applicant contended, is proof that one is not required.

Regarding the overall design of his system, the Applicant also argued that the length of distribution pipe, calculated by using the 8 min/cm T-time of the imported sand fill, is also appropriate rather than that of the impermeable clay. Again, as he noted, Clause 8.7.3.2.(2)(e) does not refer to a vertical separation to soil, therefore making the requirement to utilize the least permeable soil when calculating the length of distribution pipe also irrelevant. Moreover, as the Applicant indicated, the size of the leaching bed including mantle, allows for a loading rate of approximately 2.6 L/m^2 per day, which is well under the maximum rate of 6 L/m^2 stipulated in Article 8.7.4.1. At this application rate, there should be no horizontal movement of effluent beyond the bed area.

The Applicant also argued that his proposal made sense when considering the nature of sewage systems equipped with shallow buried trench-type leaching beds. In his view, because such systems are required to provide tertiary treatment units, the nature of filtration in the distribution bed is quite different from conventional Class 4 systems. Whereas the quality of effluent in a conventional, untreated system that reaches the tile bed is poor, in a treated, shallow buried trench system the quality of effluent dosed into the chambers is high. This significant difference means that the beds are required to function much differently. In a conventional Class 4 system, the Applicant argued, the 900 mm vertical separation also includes from soil because that amount of material is required to accomplish much of the actual filtration and treatment. On the other hand, this filtration and treatment is mostly done in the tertiary treatment unit of a shallow buried-type system, making the larger separation unnecessary. As the Applicant indicated, in a shallow buried-type system most of the disposal is done close to the surface and relies upon the plant roots and earthworm channels to move effluent laterally.

6. **Respondent's Position**

The Respondent submitted that the vertical separation is required for the proposed sewage system. In his view, while the Code is not specifically clear on the 900 mm separation from soil, nonetheless that is its intent. As he noted, if vertical separations were not necessary for shallow buried trench-type disposal systems, as the Applicant previously argued, then why does Clause 8.7.3.2.(2)(e) contain any such requirements with respect to the high ground water table and rock? The Respondent argued that the type of clay in the area (described as "bullet proof clay") is essentially like rock and would react as rock. He therefore believes it should be treated the same way under the Code, i.e. provided with a 900 mm separation. The Respondent indicated that separation to soil was perhaps inadvertently omitted in the recent drafting of the Code, but it is a consistent requirement throughout Part 8.

7. **Commission Ruling**

It is the decision of the Building Code Commission that the proposed leaching bed with absorption trenches having a vertical separation of 300 mm above soil with a percolation rate of greater than 125 minutes per centimetre provides sufficiency of compliance with 8.7.3.2.(2)(e) of the Ontario Building Code provided that:

i) A tertiary treatment unit including a sand filter is provided prior to the discharge to the leaching bed;

ii) Scientific calculations on lateral flow through the imported soil are provided to demonstrate that the water level in the leaching bed will be maintained below the trench bottom; and,

iii) The imported soil meets the minimum design requirements established in Item 2.

8. **Reasons**

i) The Building Code is silent on the distance between the bottom of the shallow buried trenches and soil with a percolation rate in excess of 125 minutes.

ii) A tertiary treatment unit is provided and the soil is not considered part of the treatment system.

iii) The use of sufficiently permeable imported sand will ensure proper distribution of the effluent over the entire bed and mantle area, ensuring that the effluent level remains below the trench bottoms.

RULING

1. **The Applicant**

   Mr. Tenzin Gyaltsan, 564069 Ontario Inc., has applied for a building permit under *Building Code Act, 1992* to construct a new retail grocery store at 15 King Street West, Village of Newcastle (Clarington), Ontario.

2. **Description of Construction**

   The Applicant is currently constructing a new, one storey, Group E - mercantile occupancy (retail grocery store), with a building area of 2,420 m^2. The building will be equipped with a sprinkler and fire alarm system. The structure is provided with four exits, only two of which are readily accessible by the public.

   There are two areas of construction in dispute. The first involves a fuel fired appliance (furnace) and whether it is required to be located in a service room. The Applicant is proposing to install his gas fired furnace suspended from the ceiling of a bulk storage and receiving room at the rear

of the supermarket. The furnace would hang directly above a number of large walk-in freezers and meat and bakery preparation areas. The Applicant does not intend to locate the furnace in a separate room that contains only building service equipment. The original approved drawing showed the furnace unit on the roof, directly above its proposed inside location.

The second involves placement and illumination levels of emergency lighting in the subject grocery store. The Applicant is proposing to install emergency lighting in the large north, south, east, and west aisles at the perimeter of the supermarket, but not in the internal, narrower, intermediate aisles between the shelving units. The Applicant originally submitted, and the permit was based on, drawings stamped by an engineer which showed that the intermediate aisles would also be provided with emergency lighting.

3. **Dispute**

There are two issues at dispute between the Applicant and Respondent. The first is whether the proposed location of the fuel fired furnace, suspended from the ceiling above walk-in freezers and food preparation facilities in a storage and receiving area of the building, complies with Sentences 3.6.2.1.(2) and 3.6.2.2.(3) of the Ontario Building Code. Sentence 3.6.2.1.(2) requires that in a mercantile occupancy in a building of this size fuel-fired appliances should be located in a service room with a one hour fire-resistance rating. Sentence 3.6.2.2.(3) provides an exception to Sentence 3.6.2.1.(2) regarding the requirement for a fire separation provided that the fuel fired appliance does not serve more than one suite, as is the case in the subject grocery store. This exception does not address whether the fuel fired appliance must still be placed in a separate service room.

The second dispute involves the proposed placement of emergency lighting in only the perimeter aisles of the supermarket and the resultant level of illumination provided and whether this complies with Clauses 3.2.7.3.(1)(i) and (j) and Sentence 3.2.7.3.(3) of the OBC. These Clauses require that an average level of emergency lighting not less than 10 1x at floor level shall be provided in principal routes to exits and in internal aisles serving as principal routes to exits. Sentence 3.2.7.3.(3) provides a minimum level of illumination at 1 1x for Sentence (1). If the internal aisles are considered as principal routes to exits then they must be provided with emergency lighting. If they are not considered principal routes then the level of illumination from the large, principal route aisles at the perimeter must be able to provide adequate lighting to be seen from the intermediate aisles.

4. **Provisions of the Ontario Building Code**

Sentence 3.6.2.1. Fire Separations Around Service Rooms

(2) Except as permitted by Article 3.6.2.2., a fuel-fired appliance in a building not containing a Group B or Group F, Division 1 occupancy shall be located in a service room which shall be separated from the remainder of the building by a fire separation having a fire-resistance rating not less than 1 h if the building is more than 2 storeys in building height or more than 400 m^2 (4,310 ft^2) in building area.

Sentence 3.6.2.2. Waiver of Fire Separations

(3) Except for buildings classified as Group B or Group F, Division 1 occupancies, the fire separations required by Sentence 3.6.2.1.(2) need not be provided for fuel-fired appliances that serve not more than one room or suite, provided the appliances are not solid fuel-fired appliances referred to in Sentence 3.6.2.1.(3).

Clauses 3.2.7.3. Emergency Lighting

(1) Emergency lighting shall be provided to an average level of illumination not less than 10 1x (0.9.ft-candles) at floor or tread level in

(i) principal routes providing access to exit in a floor area that is not subdivided into rooms or suites of rooms served by corridors in a business and personal services occupancy, a mercantile occupancy or an industrial occupancy, and

(j) internal corridors or aisles serving as principal routes to exits in a business and personal services occupancy, a mercantile occupancy or an industrial occupancy that is subdivided into rooms or suites of rooms, and is not served by a public corridor.

Sentence 3.2.7.3. Emergency Lighting

(3) The minimum value of the illumination required by Sentences (1) and (2) shall be not less than 1 1x (0.09 ft-candles).

5. **Applicant's Position**

Regarding the first dispute, the Applicant submitted that the proposed location of the furnace complies with Sentences 3.6.2.1.(2) and 3.6.2.2.(3) of the OBC. In his view, the exception concerning the provision of the fire separation found in Sentence 3.6.2.2.(3) is applicable. As he

argued, the subject furnace would serve the entire building, but which contains only one suite. As a result, the one hour fire separation can be waived. As he further argued, if the fire separation is waived there is far less rationale for locating the furnace in a service room solely designated for building services equipment. The project engineer for the subject supermarket submitted that in this experience this is the first time they have been required to treat a furnace in this manner.

Concerning emergency lighting, the Applicant argued that both Clauses 3.2.7.3.(1)(i) and (j) apply only to the principal routes leading to exits. He indicated that the only aisles that should be considered as principal routes to exits in the supermarket are the large perimeter aisles. The internal, intermediate aisles are not principal routes. He insisted that they should be considered only as floor area that accesses the principal routes. As a result, he concluded that emergency lighting should only be provided in the perimeter aisles that serve as principal routes. Lastly, the Applicant indicated that the lighting levels of the principal routes would be sufficient to be visible form the floor area in the intermediate aisles, thereby satisfying Sentence 3.2.7.3.(3)

6. **Respondent's Position**

On the first issue pertaining to the location of the fuel fired furnace, the Respondent submitted that while they recognized the applicability of Sentence 3.6.2.2.(3) that would permit the Applicant to waive the separation requirements, they indicated that, in their view, this same exception does not specifically provide for the placement of furnaces outside of service rooms. In other words, the exception found in Sentence 3.6.2.2.(2) only deals with the fire separation requirements of Sentence 3.6.2.1.(2) and does not affect the requirement of that provision for fuel fired appliances to be located in service rooms. They indicated that the proposed locating of the furnace suspended from the ceiling in storage and receiving area constitutes installation in a service space, not a service room. By placing the furnace unit in a room, even without a fire separation, offers a degree of protection that installation in an open area does not. For this reason, the Respondent felt that the proposed furnace location did not comply with Code.

Regarding the second dispute, the Respondent noted that were willing to accept the engineer stamped drawings that were originally submitted as the emergency lighting plan. They indicated that they had not received an up to date proposal by the Applicant. Nevertheless, the Respondent opposed the idea that emergency lighting is required only in the perimeter aisles which serve as principal routes to exits. They argued that emergency lighting should be provided in the intermediate aisles in accordance with Clause 3.2.7.3.(1)(j) since they form part of the principal routes to exit as well. Finally, they asserted that without emergency lighting in the intermediate

aisles it would be difficult to meet the minimum lighting levels set out in Sentence 3.2.7.3.(3) in certain parts of the floor area.

Finally, the Respondent indicated that they formed their opinions on these issues in consultation with the Housing Development and Buildings Branch and Lumacell Incorporated.

7. **Commission Ruling**

It is the decision of the Building Code Commission that the fuel fired appliance and the proposed level of illumination provides sufficiency of compliance with Sentence 3.6.2.2.(3) and Clauses 3.2.7.3.(1)(i) and 3.2.7.3.(1)(j) of the Ontario Building Code.

8. **Reasons**

i) The provisions of Sentence 3.6.2.2.(3) exempt Group E occupancies from the fire separation requirements of service rooms where the appliance does not serve more than one suit of rooms. The retail grocery store is considered only one suite as defined under Article 1.1.3.2. of the Building Code.

ii) The emergency lighting as proposed provides illumination of the principal routes in access to exits, and the aisles serving the shelves are not considered principal access routes.

iii) Design drawings confirming illumination levels will be submitted.

RULING

1. **The Applicant**

   Mr. Rick Lovekin, 1220351 Ontario Ltd., received a building permit under the *Building Code Act, 1992* to renovate a nineteenth century schoolhouse by converting it into several residential condominium units at 18 Chaple Street, Cobourg, Ontario.

2. **Description of Construction**

   The Applicant has recently renovated a two storey, 1883 Victorian schoolhouse by adding several condominium units. The Group C - residential structure with a building area of 300 m^2, is described as combustible construction and is equipped with a fire alarm system.

   The construction in dispute concerns a guard separating a loft containing a bedroom and a washroom 9 ft above the ground floor in two of the second storey units. The guard consists of two parts, an original historic lower level and a recently added steel post and rail upper level. The lower portion is composed of a wood guard that also acts as a frame for panels of iron lattice

and has a total height of 610 mm. The upper portion, recently added to achieve compliance with the current standards under the OBC, is composed of a single 50 mm diameter steel rail supported at a height of approximately 250 mm above the lower guard by upright posts located roughly every 1,200 mm. The combined total height of both the upper and lower portions of the modified guard is 915 mm. All of the area beneath the horizontal rail and between the vertical posts is open to the floor area below.

3. **Dispute**

The issue at dispute between the Applicant and Respondent is whether the modified historic guard, as constructed, provides sufficiency of compliance with Sentence 9.8.8.4.(1) and Article 9.8.8.5. of the Ontario Building Code. These provisions stipulate that the openings in a required guard cannot exceed 100 mm unless it can be demonstrated that the subject openings do not represent a hazard and that no climbable elements be placed be placed between 100 and 900 mm above the floor respectively. The openings below the horizontal rail and the vertical posts far exceed 100 mm and the iron lattice as well as the top of the lower, original guard could facilitate climbing.

4. **Provisions of the Ontario Building Code**

Sentence 9.8.8.4. Openings in Guards

(1) Except as provided in Sentence (2), openings through any guard which is required by Article 9.8.8.1. shall be of a size which will prevent the passage of a spherical object having a diameter of more than 100 mm (4 in) unless it can be shown that the location and size of openings which exceed this limit do not represent a hazard. (See A-9.8.8.4.(1) and (2) in Appendix A.)

Article 9.8.8.5. Design to Prevent Climbing

(1) Guards required by Article 9.8.8.1. and serving buildings of residential occupancy shall be designed so that no member, attachment or opening located between 100 mm (4 in) and 900 mm (2ft 11 in) above the floor or walking surface protected by the guard will facilitate climbing.

5. **Applicant's Position**

The Applicant submitted that the modified guard does not represent a hazardous situation and therefore complies with the intent of OBC 9.8.8.4.(1) and 9.8.8.5. He argued that the existing lower portion of the guard is a valued historic feature of the building and achieving complete

compliance with the disputed OBC standards would greatly diminish its historic integrity. He noted that the original guard offered protection to the occupants of the building when it was used as an assembly occupancy, specifically a Sunday school. Moreover, the Applicant indicated that the hazard has been reduced by the recent addition of the higher rail and support posts.

The Applicant indicated that the change of occupancy to residential does not represent an increased hazard over the previous use. He further argued that the existing lower portion of the guard should be considered an acceptable compliance alternative under Part 11 and be allowed to remain as is.

The Applicant indicated that the guard has existed to their knowledge without incident for over 100 years. He also stated that the recent purchasers of the two units would be upset if the guards were further modified.

Lastly, the Applicant submitted a letter indicating that the Cobourg Local Architectural Conservation Advisory Committee had recommended this project for a 1999 Ontario Historical Society award.

6. **Respondent's Position**

The Respondent submitted that the modified guard does not achieve the level of safety required by the Code. He indicated that he was concerned about both the large size of the openings in the newer part of the guard and the climbable features of the historic portion of the guard. While he recognized the Applicant's effort to reduce the level of hazard by adding the horizontal rail with vertical posts, these measures are not sufficient to allay his concerns. For these reasons, the Respondent felt he could not accept the modified guard as constructed.

7. **Commission Ruling**

It is the decision of the Building Code Commission that the modified guard as constructed with a total height of 915 mm over the existing guard provides sufficiency of compliance with Sentence 9.8.8.4.(1) and Article 9.8.8.5. of the Building Code provided:

a) the clearance between existing guard and the 50 mm rail extension complies with the maximum size openings of 100 mm.

8. **Reasons**

a) It is the opinion of the Building Code Commission that the safety issue can be addressed by the use of materials that will not adversely affect the architectural significance of the guard.

RULING

1. **The Applicant**

   Mr. Frank Macri, Franchise Director, has applied for a building permit under the *Building Code Act, 1992* to construct a new Pizza Nova Take Out franchise at Unit No. 112, Clarington Centre (Building A), Bowmanville, Ontario.

2. **Description of Construction**

   The Applicant is proposing to construct a new, 83 m^2 (4.5 m x 18.39 m), Pizza Nova Take Out franchise. The Group E - mercantile occupancy (take out outlet), as described by the Applicant, will be constructed in a leased spaced (Unit No. 112) located in Building A of the Clarington Centre. The Clarington Centre is a new, one storey, retail strip plaza containing numerous Group D - business and Group E - mercantile occupancies, with a building area of 1,187 m^2. The Pizza Nova franchise, as is the case with other tenants in the plaza, will be accessed directly from the outdoors, not from an interior corridor, and will have 1 hour fire separation demising walls

between other occupancies. The plaza is noncombustible construction and is equipped with a monitored sprinkler system, but not a fire alarm system.

In the subject Pizza Nova facility (which represents only 7% of the total building area of the entire plaza) the Applicant is proposing that 72 m^2 of the total area be devoted for food storage, preparation and sales, while 11 m^2 is to be allocated for a customer ordering area that includes a condiment ledge. There is no provision for seating which would encourage patrons to consume food and drink, or otherwise remain in the take out outlet.

The construction in dispute concerns the number and location of washrooms proposed for the franchise. The Applicant is proposing to install a single, barrier-free accessible, washroom that is intended to serve both sexes. No other washrooms will be provided within any of the public spaces of the plaza. As well, the washroom is to be placed at the rear of the take out facility, behind the food storage and preparation areas.

3. **Dispute**

The issue in dispute between the Applicant and Respondent is whether the proposed 83 m^2 fast food outlet can be considered a mercantile occupancy and would therefore be adequately served by a single, unisex barrier-free accessible washroom, in accordance with Sentence 3.7.4.8.(3) of the Ontario Building Code. This provision determines the number of washrooms required per sex for mercantile occupancies. The dispute, however, centres on whether the major occupancy of the Pizza Nova Take Out outlet should be considered an mercantile occupancy or assembly. The washroom requirements are different for these occupancies. If considered an assembly occupancy, i.e. restaurant, then an additional washroom would be required.

Further, the location of the washroom at the rear of the take out facility, beyond food preparation areas, is also at issue. Article 3.7.4.15. stipulates that washrooms should not be located where in order to access them it would be necessary to travel through food preparation areas.

4. **Provisions of the Ontario Building Code**

Sentence 3.7.4.8.(3) Plumbing Fixtures for Mercantile Occupancies

(3) Not more than one water closet to serve both sexes need be provided in a Group E occupancy where

(a) the occupant load is not more than 9 persons, or

(b) where the total area of the occupancy, excluding basements, is not more than 300 m^2 (3,230 ft^2).

Sentence 3.7.4.3.(4) Plumbing Fixtures for Assembly Occupancies

The number of water closets required for dining rooms, restaurants and cafeteria shall conform to Table 3.7.4.3.D.

Sentence 3.7.4.15.(1) Location of Plumbing Fixtures

(1) A room containing a water closet shall be located where

(a) it does not open directly into any room or area where food is intended to be stored, prepared, processed, distributed, served, sold or offered for sale, and

(b) it is not necessary for the public to go through the food preparation areas to gain access to the plumbing fixtures.

5. **Applicant's Position**

The Applicant submitted that the proposed fast food franchise should be considered a mercantile occupancy and that the provisions found under Sentence 3.7.4.8.(4) are the applicable standards. As a result, he argued that a single, unisex washroom, equipped with one water closet and one lavatory is sufficient.

The Applicant based this argument on the fact that very little space of the fast food outlet is being provided for customers and there will be no seating at all. He also referred to Hazard Index Table 11.2.1.1.K. to support his position. As he noted, this Table includes "fast food" outlets as a Group E major occupancy. Moreover, the Applicant also referred to the 1975 version of the OBC that defined a restaurant as "any portion of a building thereof where food is offered for sale for immediate consumption therein..." He indicated that the subject fast food franchise does not meet this definition.

The Pizza Nova outlet cannot be considered a restaurant since the food and drink for sale is not for immediate consumption inside, the Applicant argued. This would also mean that Article 3.1.2.6., which allows a restaurant to be classified as a mercantile occupancy if it has less than 30 persons consuming food and drink, does not apply, since no food and drink will be consumed on the premises. Article 3.7.4.3. does not apply to the subject Pizza Nova outlet since this provision,

Sentences (6) and (7) in particular, refer to the number of "seats" in a restaurant. Without seats this Article does not apply.

Sentence 3.7.4.8.(4) on the other hand, is more appropriate for determining the number of washrooms for a fast food outlet, the Applicant indicated. As he noted, the requirements for complying with this provision are that the occupant load is not more than 9 persons and the total area of the occupancy, excluding basements, is not more than 300 m^2. The proposed Pizza Nova facility meets both of these requirements. As a result, the Applicant concluded, only one washroom is necessary based on the standards for a mercantile occupancy. It is this standard that has applied to their other Ontario locations, he stated.

Lastly, the Applicant noted that the single washroom provided will meet the barrier-free accessibility design criteria found in Article 3.8.3.12.

6. **Respondent's Position**

The Respondent submitted that the proposed Pizza Nova fast food outlet should be considered as a restaurant and would thus be classified as a assembly occupancy. Consequently, In their view, a separate washroom is required for each sex. Moreover, each washroom is required to provide at least one water closet and one lavatory, and both are required to be barrier-free accessible.

The Respondent argued that the fast food outlet should be considered a restaurant because the patrons of the Pizza Nova facility may eat at the condiment ledge in the franchise itself and also in their cars in the parking lot. In fact, they point to Sentence 3.7.4.3.(10) which identify parking lots as extensions of restaurants where take out service is provided. As a result, they would consider the franchise a restaurant, but under Article 3.1.2.6. they would classify it as a mercantile occupancy since they would calculate the number of persons, including those eating in the parking lot, at not more than 30. Nevertheless, as a restaurant Sentence 3.7.4.3.(4) is applicable and it requires that two washrooms, one for each sex, be installed.

The Respondent also noted that both of the two required washrooms should be designed to bee barrier-free accessible, however they indicated that they would be satisfied if the Applicant simply provided another standard size (not barrier-free accessible) washroom.

Finally, the Respondent argued that the proposed location of the washroom, at the rear of the restaurant, does not comply with Sentence 3.7.4.15.(1), which prohibits patrons from travelling through food preparation areas to access plumbing facilities. They also referred to the Food

Premise Regulation made under the Health Protection and Promotion Act which they claim supports their assertion that the washroom is incorrectly placed behind the food preparation areas.

7. **Commission Ruling**

It is the decision of the Building Code Commission that the proposed single unisex barrier free accessible washroom to serve the fast food outlet provides sufficiency of compliance with Sentence 3.7.4.8.(3) of the Ontario Building Code provided that patrons need not go through the food preparation area to gain access to the plumbing fixtures.

8. **Reasons**

i) The fast food outlet is considered a Group E occupancy as no seating is provided for consumption of food.

RULING

1. **The Applicant**

   Mr. David McConnell, Architect, Turner Fleischer Architects Inc., Ontario, has applied for a building permit under the *Building Code Act, 1992* to construct an addition onto an existing Valu-Mart retail food store at Highway No. 36 and Boyd Street, Bobcaygeon, Ontario.

2. **Description of Construction**

   The Applicant proposes to renovate his existing 860 m^2 (9,257 ft^2), single storey, Group E - Retail occupancy by constructing a 648 m^2 (6,977 ft^2) addition on the facility's northern facade, for a total building area of 1,508 m^2 (16,234 ft^2). The building is of noncombustible construction and the proposed addition will be separated from the existing structure by a four hour firewall. The facility will be equipped with a fire alarm system but not a sprinkler system. The structure is considered to face one street.

The construction in dispute relates to the size of the expanded building and the requirement for the provision of a sprinkler system.

3. **Dispute**

The issue at dispute between the Applicant and Respondent is whether the proposed retail facility, with a building area of 1,508 m^2 (16,234 ft^2), that is not equipped with a sprinkler system, provides sufficiency of compliance with Article 3.2.2.59. of the Ontario Building Code. This provision permits a single storey building that faces one street to be unsprinklered as long as the structure has a maximum building area of 1,500 m^2 (16,100 ft^2). The subject building, including addition, exceeds this limit by 8 m^2 (134 ft^2) and is not proposed to be equipped with a sprinkler system.

4. **Provisions of the Ontario Building Code**

Article 3.2.2.59 Group E, up to 3 Storeys

(1) A building classified as Group E is permitted to conform to Sentence (2) provided

(a) it is not more than 3 storeys in building height, and

(b) it has a building area not more than the value in Table 3.2.2.59.

5. **Applicant's Position**

The Applicant submitted that the proposed structure, including addition, that exceeds the maximum allowed building area for a building of this nature, provides sufficiency of compliance with Article 3.2.2.59. of the OBC. He based this argument on the following reasons:

The area of the building in excess of the maximum allowed, at 8 m^2, he noted, is less than one per cent of the building area of the entire structure. Further, if one were to calculate the inside wall-to-wall area, the actual building area is reduced to 1,454 m^2 (15,653 m^2), which reduces the total area to within the maximum permitted. The Applicant also indicated that only 76 per cent, or 1,139 m2 (12,263 ft2), of the store is open to the public. The backroom space, consisting of food storage and packaging areas, the receiving facility and staff washrooms, is restricted to employees only.

The Applicant also argued that the exit facilities provided in the subject building are well placed on the north, east and west sides of the structure. These exit doors lead directly to the exterior, all at grade level.

In terms of compensating measures, the Applicant noted that Article 3.2.2.59. permits a building of this size and occupancy to be constructed of combustible construction. This building, while only slightly larger than the maximum building area permitted, is of entirely noncombustible construction. As well, smoke detectors connected to the building's fire alarm system will be provided, thus providing early warning in the event of a fire. This detection exceeds the requirements in the OBC for a building of this type, the Applicant stated.

For these reasons, the Applicant concluded that the proposed expanded building meets or exceeds the level of life safety required under Article 3.2.2.59. for the subject building and thereby provides sufficiency of compliance.

6. **Respondent's Position**

The Respondent submitted that the proposed unsprinklered building, with a building area of 1,508 m^2, does not comply with Article 3.2.2.59. While the Respondent recognized that the amount of excess area was minimal, he indicated that the Code requirements clearly stipulate a maximum of 1,500 m^2 for such a building. He also argued that OBC Article 3.2.2.59. does not allow him to waive this requirement when the building is noncombustible construction.

In the Respondent's view, since the subject building is only at the plans review stage, scaling the addition down by 8 m^2 is still quite feasible. This would allow the project to meet the minimum standards as found under Article 3.2.2.59., he noted.

7. **Commission Ruling**

It is the decision of the Building Code Commission that the building area of 1,508 m^2 not equipped with the sprinkler system provides sufficiency of compliance with Article 3.2.2.59 of the Ontario Building Code provided that

i) The Valu-mart store is equipped with heat detection throughout and connected to the fire alarm system,

and

ii) the fire alarm system is connected to a central monitoring station.

8. **Reasons**

i) The building is single storey (plus mezzanine) and separated from the remainder of the plaza complex by a 4 hour firewall which is understood to be in compliance with the code and is significantly less than the total area permitted under Article 3.2.2.59 of the Building Code.

ii) The building faces two streets for fire department access.

iii) Additional detection and connection to a central monitoring station is provided to allow early warning and fire department response.

iv) The building area is marginally exceeded by 8 m^2.

RULING

1. **The Applicant**

   Mr. Idwal Richards, President, Pye & Richards Architects Inc., has applied for a building permit under the *Building Code Act, 1992* to construct a new, low-rise office building, known as the Kanata Research Building, at 309 Legget Drive, Kanata, Ontario.

2. **Description of Construction**

   The Applicant proposes to construct a new, three storey, Group D - office occupancy with a building area of 2,036 m^2. A portion of the structure will also contain a Group F, Division 3 - low hazard industrial occupancy. The building will be noncombustible construction. It will be equipped with a fire alarm and sprinkler system.

   The construction in dispute concerns the proposed fire separation, which is not required to have a fire-resistance rating, that is to enclose the duct shafts (vertical service space) throughout the three storey building. The Applicant proposes to install an assembly consisting of one layer of

12.7 mm drywall on only one side of 92 mm steel studs. This assembly would be taped and sealed at the perimeter and all penetrations.

3. **Dispute**

The issue at dispute between the Applicant and Respondent is whether the proposed fire separation assembly, that is not required to have a fire-resistance rating, complies with Sentence 3.6.3.1.(1) of the Ontario Building Code. This provision requires that the separation for the vertical service space be determined based on the rating of the floor assembly required for the subject building as found in Table 3.6.3.1. In the building at dispute, since the floor assemblies are permitted to have a rating of less than 45 minutes, Table 3.6.3.1. indicates therefore that the vertical service space is not required to have a fire-resistance rating, in other words it is permitted to be an unrated fire separation. The issue thus centres on whether the proposed assembly for the vertical service space can be considered an unrated separation and whether it would perform as required by the Ontario Building Code.

4. **Provisions of the Ontario Building Code**

Sentence 3.6.3.1. Fire Separations for Vertical Service Spaces

(1) Except as required by Section 3.5., a vertical service space shall be separated from all other portions of each adjacent storey by a fire separation have a fire-resistance rating conforming to Table 3.6.3.1. for the fire-resistance rating required by Subsection 3.2.2. for

(a) the floor assembly above the storey, or

(b) the floor assembly below the storey, if there is no floor assembly above.

5. **Applicant's Position**

The Applicant submitted that the proposed fire separation, with drywall on one side only, provides sufficiency of compliance with Sentence 3.6.3.1.(1) of the OBC. They offered the following arguments to support this view.

At the outset the Applicant indicated that both he and the Respondent agree that the subject noncombustible building is not required to have floor assemblies with a rated fire separation. Referring to Table 3.6.3.1., it follows, he also indicated, that both parties agree that the vertical shaft walls are permitted to be separations without a fire-resistance rating.

In the Applicant's view, as an unrated separation, the subject assembly is required to act as primarily a smoke barrier with minimal ability to withstand fire. In terms of providing a barrier to smoke, he argued that the vertical service shaft constructed with a single layer of drywall on the outside and taped and sealed at the perimeter and at all penetrations is sufficient. Because the proposed separation is considered noncombustible and is continuous and completely sealed, it is entirely adequate to perform this function.

The Applicant also argued that it does act to some degree as a barrier against the spread of fire in accordance with the definition of fire separation found in Article 1.1.3.2. and A-3.1.8.1. (1)(b) of the OBC Appendix, the latter of which requires a separation to stay in place "until some response is initiated." He indicated that an assembly with drywall on one side would likely stay in place for approximately 10 to 15 minutes (even with a fire occurring on the inside of the service shaft), which would be long enough to withstand fire until the sprinklers have activated.

The Applicant offered correspondence from the Canadian Codes Centre and the Ministry's Housing Development and Buildings Branch which indicated that the proposed assembly would comply with the requirements for an unrated separation.

Lastly, the Applicant argued that the construction of the proposed assembly is quite common and is accepted in other municipalities throughout the province.

6. **Respondent's Position**

The Respondent submitted that the proposed vertical service shaft separation assembly does not comply with Sentence 3.6.3.1.(1).

As they argued, since the enclosure around the vertical service space is considered a fire separation, it must meet the definition of fire separation in the OBC, which is an assembly that "acts as a barrier against the spread of fire". The Respondent also point to the OBC Appendix which indicates that a fire separation should perform its function until some response is initiated, i.e., activation of the sprinkler system. To perform its function as a separation until the sprinkler system is activated means that the assembly must remain in place for approximately 15 minutes. In other words, even an unrated separation requires at least some degree of fire-resistance rating. In their view, however, the steel studs of the proposed assembly, when exposed to fire from the inside, would likely fail well before sprinkler activation.

In order therefore to meet the intent of Sentence 3.6.3.1.(1) they argued that the separation requires a layer of drywall on both sides. Only by having drywall on both sides will the separation have some form of protection from fire exposure from both directions and would therefore ensure its integrity. To support this, the Respondent pointed to OBC Sentence 3.1.7.3.(2) and 2.3.5.(1) of the Supplementary Guidelines, which they argued indicate that interior vertical fire separations should be rated for fire exposure from both sides.

The Respondent also raised concern regarding the structural requirements of the shaft walls. They pointed to Sentence 4.1.10.3.(1) which requires the subject walls to be able to withstand the appropriate lateral design loads. They indicated that unless the vertical service walls were protected from fire exposure on both sides, the steel studs would be significantly weaken and would collapse within minutes. The Respondent submitted a letter from a structural engineering consultant supporting this position.

In conclusion, the Respondent argued that any vertical fire separation, including those permitted to be unrated, must act as a barrier to smoke, and to some degree, fire in order to be able to perform as a separation. Moreover, the only way to achieve this is to have a membrane on both sides of the assembly that would provide a greater degree of over all fire-resistance rating for the assembly and would offer more protection to the structural members.

7. **Commission Ruling**

It is the decision of the Building Code Commission that the vertical shaft construction provides sufficiency of compliance with Sentence 3.6.3.1.(1) of the Building Code.

8. **Reasons**

1) The building is noncombustible and sprinklered throughout.

2) The ducts penetrating the shaft are noncombustible.

3) The duct shaft is taped and sealed to act as a smoke barrier.

4) The shaft contains no combustible material.

5) The combination of exterior shaft and duct penetrations provide a barrier to smoke and fire spread consistent with A-3.1.8.1.(1) of the Ontario Building Code Appendix.

For the Respondent

RULING

1. **The Applicant**

   Mr. Bill Koppens, homeowner, Schomberg, Ontario, was issued an order to comply under the Building Code Act, 1992 regarding certain work undertaken at his residence specifically pertaining to the excavation of soil, insulation installed on a portion of the basement foundation wall, the erection of a patio retaining wall and the enclosure of the patio at 6596 Highway No. 9, Schomberg, Ontario.

2. **Description of Construction**

   As part of other alterations being carried out at the Applicant's single storey, Group C - residential occupancy, an existing enclosed below grade basement entrance was renovated by adding a new enclosed walkout patio.

   The construction in dispute entailed excavating the soil backfilled against the eastern half of the north face of the basement foundation wall so that repair work could be conducted on a portion

of the subject foundation wall, including footings, adjacent to either side of the existing basement door which had been damaged due to frost. The applicant stated that rigid 50 mm (2 in) Styrofoam SM insulation was then extended 915 mm (3 ft) vertically below into the soil on the same plane as the foundation wall.

The work also involved the creation of a basement level concrete slab walkout patio approximately 6.1 m (20 ft) in width at the rear, or north-east corner, of the house that roughly centred around the subject basement door. The applicant stated that styrofoam (50 mm) insulation was also installed horizontally across the width of the patio under the concrete slab extending approximately 1,200 mm (3 ft, 11 in) from the foundation wall.

Retaining walls, much of which exceed 1,000 mm (3 ft, 3 in) in exposed height (1,200 mm at their highest points), were constructed on either side of the subject patio. The new retaining walls have footings 1,200 mm deeper than the previous retaining wall footings. The east retaining wall in particular separates the patio from an adjacent driveway. The trenches for the retaining walls were dug below the level of the footings for the house foundation wall. The exterior of the retaining walls were also lined with 50 mm Styrofoam insulation. The patio was then completely enclosed with a fibreglass roof and steel and glass partition walls. The enclosure is considered unconditioned space.

The above described work was not included in the building permit application nor was it inspected until after it was constructed.

3. **Dispute**

The issue at dispute between the Applicant and Respondent is whether the foundation wall, including the insulation, and the patio retaining walls were built in accordance with Sentence 9.12.2.2.(1) and Part 4 respectively of the Ontario Building Code. Sentence 9.12.2.2.(1) sets out the minimum depth of foundations required in certain types of soils to ensure that, in part, protection from frost is provided. For the subject building the foundation depth required is 1,200 mm. The patio concrete slab, however, is located at approximately the same depth as the footings, thus making the footings potentially vulnerable to frost damage. Frost protection for the footing is therefore required below the patio where the foundation was exposed.

The issue regarding the retaining walls is that since much of the length of the wall is higher than 1 m and is adjacent to access to a building, they are therefore considered designated structures under the OBC. Further, because the trenches for the retaining wall were excavated below the

level of the foundation footing, the wall, as built, extends into the angle of repose of the existing footing. Part 2 of the OBC requires a professional engineer to design work of this nature.

The work on both the foundation and retaining walls were covered before the municipality could inspect the work.

4. **Provisions of the Ontario Building Code**

Sentence 9.12.2.2. Minimum Depth of Foundations

(1) Except as provided in Sentences (4) and (5), the minimum depth of foundations below finished ground level shall conform to Table 9.12.2.2.

5. **Applicant's Position**

The Applicant submitted that work done on the foundation wall and the construction of the two retaining walls complied with Sentence 9.12.2.2.(1) and Part 4 of the OBC.

Regarding the foundation footings, he argued that the reason that patio with its retaining walls was created was to repair frost damage to the basement foundation footings that had occurred due to the previous poorly constructed basement entrance. For this reason, the Applicant stated that he was careful to ensure that the new work would prevent such frost related problems from occurring. The horizontal and vertical insulation placed under the patio slab and extending downward and in front of the footing will more than adequately protect the footing from frost damage, he argued. Further, the glass and steel enclosure will protect the slab and the footings from moisture.

The Applicant submitted letters from a contractor (who visited the site but was not involved in the actual work) and from an engineer known to this contractor that indicated that the insulation method was adequate. The engineer added, however, that the basement must be heated to a minimum temperature of five to six degrees Celsius (45o F) in order so that the soil directly below the basement does not freeze. The Applicant indicated that the engineer had not been professionally retained to inspect the work or approve of its design.

On the subject of the retaining walls, the Applicant also pointed to the letter from the contractor indicating that they were constructed in a manner more than sufficient to meet Code. He submitted photographs of the construction of the retaining walls. The Applicant also added that

under OBC Article 9.15.4.1. the patio slab could be viewed as providing lateral support to both retaining walls from the interior countering the soil pressure outside of the patio walls.

In general, he argued that the performance level of the foundation, including footings, and the retaining wall was not reduced and was, in fact, improved.

Lastly, the Applicant indicated that he believed that the scope of the work done on the patio was covered by the existing building permit. Further, he argued that the inspector had not indicated that he should cease work and that the Order to Comply did not get issued until two weeks later. By which point the work had been completed.

6. **Respondent's Position**

The Respondent submitted that they were unsure as to whether the disputed constructed undertaken complied with the OBC since the work was not included on the building permit and much of it was done without inspection. As he stated, there was nothing in the permit application to indicate that a 6.1 m enclosed patio sided by two roughly 1 m high retaining walls was proposed. He indicated that he had concerns with the method of frost protection and that no underpinning of the existing foundation was done when the retaining walls were built extending into the angle of repose of the foundation. The Respondent indicated that he had been requesting a report from a professional engineer to verify that the foundation and retaining wall work met good engineering practice. He indicated that such a report would still satisfy his concerns.

7. **Commission Ruling**

It is the decision of the Building Code Commission that the patio foundation and retaining wall and a portion of the basement foundation wall as constructed provides sufficiency of compliance with Sentence 9.12.2.2.(1) and the structural requirements of Part 4 of the Building Code provided that:

i) a licensed professional engineer is engaged to review the as constructed conditions and certify that the noted code references are complied with.

8. **Reasons**

i) Although numerous photographs, letters and sketches were presented as evidence, the information was considered incomplete.

ii) ii) The municipality has outlined the willingness to accept an engineers report in correspondence dated December 21, 1998 to satisfy the remaining issues.

RULING

1. **The Applicant**

   Mr. Jim Whitehead, General Manager, Facility Development, YMCA of Greater Toronto, Toronto, Ontario, received a building permit under the *Building Code Act, 1992* to construct a YMCA community centre and athletic facility at 20 Union Street, Brampton, Ontario.

2. **Description of Construction**

   The Applicant has recently constructed a two storey (plus basement), Group A - Division 2 YMCA community centre and athletic facility with a building area of 3,018 m^2 (32,473.7 ft^2). The building is of noncombustible construction and is equipped with a sprinkler system, a fire alarm system, but not a standpipe and hose system.

   The construction in dispute is the mounting height of the manual pull stations for the fire alarm system, which were installed by the Applicant at 900 mm. Certain pull stations have also been

equipped with a UL listed tamper-proof cover that makes a loud noise when the cover is lifted. The covered pull stations are located at the main entrance and immediately outside the daycare.

The building is designed to provide barrier-free accessibility.

3. **Dispute**

The issue at dispute between the Applicant and Respondent is whether the manual pull stations, mounted at a height of 900 mm consistent with Article 3.7.1.5. of the 1990 Ontario Building Code, provides sufficiency of compliance with Sentence 3.2.4.5.(1). Article 3.7.1.5. stipulates that the installation of building services and safety devices, including fire alarm pull stations, in a barrier-free path of travel must be mounted at not more than 1,200 mm above the floor. Sentence 3.2.4.5.(1), on the other hand, requires that fire alarm systems, including pull stations, be installed according to CAN/ULC-S524-M91, "Standard for the Installation of Fire Alarm Systems". This standard, specifically in Clause 5.2.1., states that fire alarm pull stations must be placed between 1,200 mm and 1,400 mm above the floor. Located at 900 mm, the subject pull stations meet the Section 3.7 barrier-free requirements but not the referenced standards found in CAN/ULC-S524-M91.

4. **Provisions of the Ontario Building Code**

Article 3.7.1.5. Controls

Except as provided in Article 3.7.3.5., controls for the operation of building services or safety devices, located in a barrier-free path of travel and intended to be operated by the occupant, including manual pull stations, electrical switches, thermostats and intercom switches, shall be accessible to a person in a wheelchair and shall be mounted at not more than 1.2 m (3 ft 11 in) above the floor.

Sentence 3.2.4.5.(1)Installation and Testing of Fire Alarm Systems

(1) Fire alarm and voice communication systems shall be installed in conformance with CAN/ULC-S524-M, "Standard for the Installation of Fire Alarm Systems".

5. **Applicant's Position**

The Applicant submitted that mounting height of the fire alarm pull stations, as installed, meets the intent of Article 3.7.1.5. and therefore provides sufficiency of compliance with the OBC. He

argued that since the building was designed to provide barrier-free accessibility, the provisions of Section 3.7 were applicable. In his view, Article 3.7.1.5. provides a maximum height above which the pull stations may not installed, but it does not indicate a minimum height. This implies that any height less than 1,200 mm is acceptable, as long as the height also meets the criteria of being "accessible to a person in a wheelchair" as well.

To support his assertion, the Applicant pointed to the diagrams in the Illustrated Guide of the current (1997) OBC. The Illustrated Guide, he noted, clearly describes 1,200 mm as a maximum mounting height. Further, the Applicant also pointed out that other building services and safety devices, such as elevator control buttons (e.g., stop and emergency buttons) must be located at the bottom of the elevator control panel and not less than 890 mm above the floor. In other words, the Applicant argued, these vital control buttons must be placed at or around the 900 mm level.

The Applicant cited Article 2.6.2.1., which states that "in the case of a conflict between the provisions of this Code and those of a referenced document, the provisions of this Code shall govern." Because Article 3.7.1.5. is an actual provision within the OBC, whereas the CAN/ULC-S524-M91 is an external standard referenced in the Code, Article 3.7.1.5. should take priority as the guiding requirement.

Lastly, the Applicant indicated that he had sought clarification regarding the appropriate mounting height from the municipality prior to their installation. He indicated his intention to install them at 900 mm. At that time, he was told that the pull stations must not be higher than 1,200 mm, which was consistent with Article 3.7.1.5. The Applicant took this as

confirmation of the proposed height and proceeded to set the pull stations at 900 mm. It was only during a later inspection that the municipality advised him that they were too low.

6. **Respondent's Position**

The Respondent submitted that the pull stations, set at 900 mm, do not conform with the requirements of the OBC. While they recognize that two independent, and largely differing OBC requirements set out standards for pull station mounting heights, the two requirements are consistent in that they both allow a mounting height of 1,200 mm. At this height one can meet both Article 3.7.1.5. and the CAN/ULC-S524-M91 standard. In their view, therefore, 1,200 mm is the only acceptable mounting height in a building and that this mounting height is appropriate for both ambulatory and wheel chair users.

Moreover, the OBC does not contain any other acceptable benchmarks that establish specific minimum mounting heights for safety devices such as fire alarm pull stations, the respondent argued. In other words, no where in the Code does it specifically support a mounting of 900 mm, or anything less than 1,200 mm for that matter. With out a minimum height requirement, such as 1,200 mm, pull stations could be mounted dangerously low. They argued that even mounted at 900 mm, and especially since some of them are equipped with a tamper proof cover, occupants might not recognize the pull stations in the case of an emergency.

7. **Commission Ruling**

It is the decision of the Building Code Commission that the fire alarm pull stations installed at a height of 900 mm in locations described in Article 3.7.1.5. of the Building Code provides sufficiency of compliance with Sentence 3.2.4.5.(1) of the Building Code on the provision that a directional sign is located directly above the pull station at a height of 1,200 to 1,400 mm.

8. **Reasons**

i) The Building Code Article 3.7.1.5. is specific with respect to the maximum mounting distance from the floor level but does not specify a minimum distance. The 900 mm distance is consistent with universal access.

ii) The sprinkler heads in this fully sprinklered building are connected to the fire alarm system via flow switches which provides a level of detection over and above the coverage required for fire alarm systems under Section 3.2.4. of the Building Code.

iii) A directional sign is required above the pull stations at a height consistent with the installation requirements for pull stations not subject to the exemption of Article 3.7.1.5.

iv) The applicant provided evidence that the mounting height of 900 mm is consistent

with research which indicated that this is an acceptable height for ambulatory and wheelchair users, as also evidenced by the C.S.A. B.44 "Safety Code for Elevators" in serving its intended function.

RULING

1. **The Applicant**

   Ms. Sharon Gregory, President, Shardon Building Corporation, Kanata, Ontario, received a building permit under the Building Code Act, 1992 to construct an eighteen unit residential townhouse condominium project at 387 - 393 Bell Street South, 12 - 24 MacLean Street, and 395 Bell Street South (Units 1 - 13), Ottawa, Ontario.

2. **Description of Construction**

   The Applicant is currently constructing a low-rise, two storey (plus basement), Group C - residential condominium project, with a total of 18 attached units. While the individual units range in size from 39.5 to 46.5 m^2 (425 to 500 ft^2), the entire structure is divided into two parts with building areas of 598 and 269 m^2 (6,434.5 and 2,894.5 ft^2), which are separated by a firewall. The units are of combustible construction and are not equipped with a fire alarm system nor a sprinkler system.

The construction in dispute concerns the ceiling heights in the basement level bathrooms of 14 of the 18 units. A ceiling mounted overhead duct in these units resulted in a lowering of the ceiling height. The reduction of ceiling heights ranges between the affected units. Seven of the units have ceiling heights ranging between 1,950 mm (6 ft 5 in) and 2,037 mm (6 ft 8 1/2 in), while the headroom in the other seven measures between 2,037 mm (6 ft 8 1/2 in) and 2,075 mm (6 ft 10 in). The disputed bathrooms contain a lavatory, water faucet and shower stall. All of the subject units are provided with another three piece bathroom on the second floor.

3. **Dispute**

The issue at dispute between the Applicant and Respondent is whether the as constructed basement level bathroom ceiling heights, which vary between 1,950 mm and 2,075 mm, provide sufficiency of compliance with Article 9.5.2.1. of the 1990 Ontario Building Code. This provision sets out in Table 9.5.2.A. the required heights for rooms or spaces in residential occupancies. For bathrooms, Table 9.5.2.A. stipulates that the minimum height must be 2,100 mm (6 ft 11 in). Nevertheless, this provision appears to deal with bathrooms that are located above grade. Table 9.5.2.A. also describes the necessary height of basement areas. Specifically, it states that 75 per cent of a basement area must be at least 2,100 mm in height and that in areas served by ducts the height can be reduced to 1,950 mm.

At dispute then is whether a below grade bathroom must conform to the required height for bathrooms (2,100 mm), or whether the general height requirements for basement can be applied. If the disputed bathroom ceiling heights are not found to sufficiently comply with Article 9.5.2.1., extensive demolition of the concrete floor slab in the basement may be required.

4. **Provisions of the 1990 Ontario Building Code**

Article 9.5.2.1. Heights of Rooms or Spaces

(1) Heights of rooms or spaces in residential occupancies shall conform to Table 9.5.2.A.

5. **Applicant's Position**

The Applicant submitted that the basement level bathrooms with ceiling heights less than 2,100 mm provide sufficiency of compliance with Table 9.5.2.A. of the OBC. They presented the following arguments as the basis for sufficiency of compliance.

First, units of this size are only required to have one washroom as per the OBC. The bathroom on the second floor of each unit is a full, three piece facility and conforms to all requirements, including ceiling height. The basement level bathrooms are therefore, they argued, provided for convenience purposes. Moreover, the Applicant asserted that the second floor bathrooms would be the primary washrooms since they are closer to the sleeping rooms and living areas within each of the units.

Secondly, ceiling heights of 1,950 mm do not make a room or space unusable. In fact, the Applicant noted that the Code specifically recognizes that basement ceiling heights may need to be reduced in certain areas due to mechanical or structural reasons. The situation of reduced ceiling heights, they pointed out, is not only recognized for new construction in Table 9.5.2.A., but is extended even further under Compliance Alternative C88.1 found in Part 11 of the 1990 OBC. This provision allows a 1,950 mm ceiling height throughout certain renovated dwelling unit types which are more than five years old.

Thirdly, the reduced ceiling height in the bathrooms is not a safety issue. As they argued, if the Code permits a full 25 per cent of a basement area to be reduced in height to 1,950 mm to accommodate ducts and beams in new construction, then the lowered ceiling must be viewed more as an issue of convenience. The disputed ceilings would not cause any more inconvenience than any other area of the basement where the ceiling height may be restricted, the Applicant noted.

The Applicant also offered some background as to how the subject construction dispute arose. In their reading of Table 9.5.2.A. the prescribed ceiling heights for bathrooms appeared to apply to those located above grade only. As a result, their design followed the height requirements for basement areas which, in their view, permitted a reduction to 1,950 mm specifically beneath ducts. The municipality, they claimed, had originally approved the plans on the basis of this height exception. Some time soon after occupancy permits had been issued for the first units to be completed, the municipality then indicated that the basement level ceiling heights should 2,100 mm, consistent with a bathroom located elsewhere in the house. At this time, however, construction had proceeded past this point in the unfinished units.

The Applicant also indicated that they had proceeded in good faith and believed they were complying with the Code. Due to the nature of the problem and lateness of when it was discovered during the job, their options to rectify it were severely limited. They stated that lowering the floor level would be very expensive.

Lastly, the Applicant indicated that most of the units remain to be sold and that the prospective buyers would obviously have the opportunity to inspect the as built condition before purchasing.

6. **Respondent's Position**

The Respondent submitted that the subject basement level bathroom ceilings do not meet the standards set out in Table 9.5.2.A. In their view, a ceiling height of 2,100 mm is required. They indicated, however, that they shared the Applicant's view that one could perhaps interpret Table 9.5.2.A. to read that the 2,100 mm standard applied to above grade washrooms only.

The Respondent noted that the submitted plans showed a basement ceiling height of 2,400 mm (8 ft 0 in), which after the floor slab was poured and the walls framed would leave a 2,100 mm headroom in the basement. They indicated that it was construction circumstances relating to the narrowness of the units that caused the difficulties with the ducts with an enclosing bulkhead being located in the bathrooms, thereby causing a lowering of the ceiling height.

They stated they were aware of at least one purchaser who was concerned about the low bathroom ceiling height.

Nevertheless, the Respondent indicated that they felt the Applicant's arguments concerning sufficiency of compliance did have merit, however, they did not believe that they had the authority to accept the proposal.

7. **Commission Ruling**

It is the decision of the Building Code Commission that the proposed basement bathrooms with a minimum ceiling height of 1950 mm (6 ft 5 in), provides sufficiency of compliance with Article 9.5.2.1. of the Ontario Building Code.

8. **Reasons**

i) Only bathrooms, water closet rooms or laundry areas which are located above grade are required to be 2,100 mm in any area where a person would be normally in a standing position.

ii) For basements, the minimum ceiling height over 75 percent of the basement area is at 2,100 mm, except that the clearance may be reduced to 1,950 mm under beams and ducts. Therefore, 25 per cent of the floor area may be reduced to 1950 mm, and this basement area complies with this condition.

iii) The low ceiling is a result of the location of the duct work above the washroom. The building official indicated that locating the ducts in any other area, would compromise the headroom at stairs and circulation paths.

RULING

1. **The Applicant**

   Mr. Jim Podd, Director, Campus Development, Lakehead University, has applied for a building permit under the *Building Code Act, 1992* to construct a new, three storey office and laboratory facility at the Northwestern Ontario Technology Centre, Lakehead University, 955 Oliver Road, Thunder Bay, Ontario.

2. **Description of Construction**

   The Applicant proposes to construct a new, three storey (plus basement) structure with a building area of 616.4 m^2 (6,632.5 ft^2). Two occupancies are proposed for the building; Group D - business (office) and Group F, Division 3 - low hazard industrial (laboratory). The building is proposed to be of combustible construction and will be equipped with a fire alarm system and a

partial sprinkler system located only in the interconnected floor areas adjacent to the building's atrium, but not a standpipe and hose system.

The concept behind the development of the building is to act as an incubator to allow new businesses to grow and develop under the auspices of the Northwestern Ontario Technology Centre (NOTC). Each business' "incubation" period will last for a period of not more than three years. As owner of the building, the NOTC will provide general reception and administrative services. The NOTC also offers marketing, networking and funding application assistance to the individual business tenants. The actual leased office spaces, however, are under the control of the tenants.

The Applicant's intention regarding the design of the building is to create a working space to foster the growth of innovative and creative new business ventures. As a result, the building, in plan, is roughly shaped like a triangle and a full height atrium is located in the centre of the structure. A public corridor surrounds the atrium on the second floor. The Applicant is proposing that this corridor be open to the atrium and would therefore be considered interconnected floor space. The individual suite doors would open onto this second floor corridor. The two exit stairs serving the second floor are to be located on the same side of the building and would be accessed by the atrium corridor. This is not an issue on the third floor because there the atrium is separated from the floor space by a glass and drywall partition.

3. **Dispute**

The issue at dispute between the Applicant and Respondent is whether the new business ventures, although sharing many services, should be considered separate tenancies within individual suites according to the Ontario Building Code and as a result whether the public corridor located on the second floor is required to be separated from the remainder of thefloor area and from the atrium as per Article 3.3.1.4. This provision requires that in the case of the subject building, with only a required 45 minute separation between floors, but which is not entirely sprinklered, that a fire separation with a fire-resistance rating of 45 minutes be provided between the corridor and the rest of the floor area. This requirement, however, would apply in part in this case if the building was deemed to contain multiple suites. The Applicant is also offering sprinkler protection in the areas considered interconnected floor space, including the second floor open corridor.

4. **Provisions of the Ontario Building Code**

Sentence 3.3.1.3.(8) Means of Egress

(8) Except as permitted by Sentences 3.3.4.4.(6) and (7), each suite in a floor area that contains more than one suite shall have

(a) an exterior exit doorway, or

(b) a doorway

(i) into a public corridor, or

(ii) to an exterior passageway.

Article 3.3.1.4. **Public Corridor Separations**

(1) Except as otherwise required by this Part or permitted by Sentences (2) to (7), a public corridor shall be separated from the remainder of the building by a fire separation having a fire-resistance rating not less than 1 h. (See Appendix A.)

(2) The fire-resistance rating of a fire separation between a public corridor and the remainder of a floor area is permitted to be less than 1 h but not less than 45 min provided the fire-resistance rating by Subsection 3.2. is permitted to be less than 1 h for

(a) the floor assembly above the floor area, or

(b) the floor assembly below the floor area, if there is no floor assembly above.

(3) If a floor area is sprinklered, no fire-resistance rating is required for a fire separation between a public a corridor and the remainder of the floor area provided the corridor does not serve a care or detention occupancy or a residential occupancy. (See A-3.1.8.1.(1)(b) in Appendix A.)

(4) If a floor area is sprinklered, no fire separation is required between a public corridor and the remainder of the floor area provided the public corridor

(a) is more than 5 m (16 ft 5 in) in unobstructed width, and

(b) does not serve

(i) a care or detention occupancy, or

(ii) a residential occupancy.

(5) If a floor are is sprinklered, no fire separation is required between a room or a suite and a public corridor that serves it provided the public corridor complies with Sentence 3.3.1.9.(6).

(6) A floor assembly of a public corridor above a crawl space that conforms to Sentence 3.2.2.9.(2) is not required to be a fire separation.

(7) If a floor are is sprinklered, no fire separation is required between a public corridor and a room containing water closets and lavatories provided the room and the public corridor are separated from the remainder of the floor area by a fire separation that has a fire-resistance rating not less than that required between the public corridor and the remainder of the floor area.

(8) The sprinkler system in Sentences (3), (4), (5) and (7) shall be electrically supervised in conformance with Sentence 3.2.4.9.(2) and, upon operation, shall cause a signal to be transmitted to the fire department in conformance with Sentence 3.2.4.7.(4) when the corridor serves a Group E or Group F, Division 1 or 2 occupancy.

5. **Applicant's Position**

The Applicant submitted that the proposed new business ventures, while carrying their own "business names", are all part of the NOTC operation. The NOTC is the umbrella organization, under which all of the business ventures thrive. In his view, therefore, they all belong to the same organization which has a single tenure in the entire building. As a result, he argued that they conform to the definition of suite as described in the OBC, especially Appendix A.1.1.3.2. He stated that the level of safety of NOTC building occupants is not reduced because the occupants hold different "business names".

The Applicant also noted that they are proposing to sprinkler the interconnected floor areas, including the subject open corridor, which would allow safe egress from the second floor. He argued that this partial sprinkler system would compensate for the lack of fire separations between the businesses and the corridor and the corridor and the atrium.

6. **Chief Building Official's Position**

The Respondent submitted the proposed office areas serving the business ventures should be considered as suites. As they noted, despite the many shared services, the actual space occupied on a floor is entirely controlled in terms of use and access by the individual business ventures.

They also noted that each business is to have its own lease agreement and would pay rent. This is not how a single tenant building would function. In their view, by simply belonging to a larger umbrella organization does not make it possible to waive the requirement for compliance regarding suite and public corridor compliance.

As such, they argued that the public corridor system must be separated from both the adjacent floor areas and the atrium. This would entail closing off the proposed open second floor corridor, they indicated. Further, since the sprinkler system is only covers part of the building the separations must have a fire-resistance rating of at least 45 minutes.

7. **Commission Ruling**

It is the decision of the Building Code Commission that second floor laboratory and office tenancies provide sufficiency of compliance with 3.3.1.3.(8) and Article 3.3.1.4. on the condition that the floor area is sprinklered throughout.

8. **Reasons**

i) The various tenants normally are considered separate suites. However, considering the limited size, intended function and flexibility of the second floor area, the space is considered as only one tenant.

ii) Since these are not considered separate suites as discussed in reason 1, the provisions of 3.2.8.2.(6) permit exiting through the interconnected floor space.

iii) This decision is based on the proposed use as a technology centre which requires shared amenities and services to function effectively.

iv) The floor area is fully sprinklered.

RULING

1. **The Applicant**

   Ms. Denise Orlando, Corporate Real Estate Manager, Data General Corporation has applied for a building permit under the *Building Code Act, 1992* to renovate a portion of their leased space within an existing low-rise office complex, known as the DuPont Building, 7070 Mississauga Road, Mississauga, Ontario.

2. **Description of Construction**

   The Applicant is proposing to renovate their existing tenant space on the third floor of a Group D - Business occupancy in order to create a self-contained suite that can be sublet to another tenant. The Data General Corporation currently leases a total of approximately 2 434 m^2 (25 836 ft^2) in the subject building. The sublet area (intended for a Apak Systems Ltd.) is to 518 m^2 (5 575 ft^2). Data General's remaining area would be approximately 1 916 m^2(20621 ft^2).

The building itself is described as three storeys in building height, and has a building area of approximately 5 000 m^2 (53 800 ft^2). The building is of noncombustible construction. It is equipped with a smoke control, standpipe and hose, fire alarm and sprinkler systems. The fire alarm and sprinkler systems are electronically supervised, with the former having a signal that transmits to the fire department.

There are five separate atria in the building that extend the full height of the building. Due to these atria, the entire third floor area is considered interconnected floor space. Both the Data General and Apak Systems offices will be arranged with walled offices at the perimeter of the floor area, while open plan office areas will occupy the middle portions of their respective suites. The open plan office areas in both suites face two separate atria that connect to floor areas below.

The construction in dispute involves the creation of a public corridor on the south-east portion of the floor where the two suites are adjacent to each other. The proposed corridor is to be located beside an existing exit stair. Both the Data General and Apak Systems offices are to have an egress door leading to this corridor. Both egress doors will be unlocked during business hours. The subject public corridor is served by two elevators, which are located beyond the suite's egress doors in the direction exit travel. The corridor, as designed, provides only one exit stairway.

Each suite has access to other exit stairs on the floor area, and the Data General office has its own exit stair at the west end of its offices. However, the second egress route to be provided for the Apak Systems office is also in dispute. This proposed exit leads from the north of the Apak Systems suite into a circular public corridor that follows the perimeter of the rotundaatrium. While this public corridor does have access to two exit stairs, both exits are in the same direction away from Apak Systems north egress door. Three separate suites have access to the rotunda corridor.

3. **Dispute**

The issue at dispute between the Applicant and Respondent is whether the proposed design of the sublet space, especially the public corridor serving two suites, that provides only one exit, provides sufficiency of compliance with Sentence 3.3.1.3.(9) of the Ontario Building Code. This provision requires that an egress doorway that opens into a public corridor must have two separate exits in opposite directions from the egress doorway. In the proposed design one public corridor is served by only one exit stair, and the other has both exits in the same direction, therefore both are considered dead end corridors.

Provisions of the Ontario Building Code

Sentence 3.3.1.3.(9) Means of Egress

(9) Except as permitted by this Section and by Sentence 3.4.2.1.(2), at the point where a doorway referred to in Sentence (8) opens onto a public corridor or exterior passageway, it shall be possible to go in opposite directions to each of 2 separate exits.

4. **Applicant's Position**

The Applicant submitted that the proposed layout of the subject sublet space, including the single exit public corridor served by two suites, provides sufficiency of compliance with Sentence 3.3.1.3.(9) of the OBC. He argued that the intent of this provision is to ensure that all suites on a multi-tenanted floor area are provided with two exits each, and in his view both suites meet this requirement.

The Applicant noted that Sentence 3.3.1.3.(9) contains certain exceptions. In particular, he pointed out that where it refers to "this Section" means all of Section 3.3, "Safety Within Floor Areas", of the OBC. He interpreted this to mean that all options within Section 3.3 which provide access to two separate exits serving each suite in a floor area, and therefore consistent with the intent of 3.3.1.3.(9), can stand as exceptions to that Sentence.

The Applicant asserted that Sentence 3.3.1.3.(9) offers protection to those suites on a multi-tenanted floor area that have a single egress door by allowing a choice of exit routes in their only accessible public corridor. Moreover, he added that this provision also protects larger suites that are required to have more than one egress doorway and which may open on the same public corridor. The same principle is evident in Sentence 3.3.1.9.(11), he noted, as it protects suites in buildings with a single public corridor by reducing the potential of creatinglong dead end corridors.

Building on this premise, the Applicant then argued that both suites have access to more than two exits. The Data General and the Apak Systems offices have access to three and two possible exit stairs respectively, not including the proposed single exit public corridor. This number of exits would more than adequately serve the occupant load of the two suites, which he described as approximately 40 for Data General and 20 for Apak Systems. Further, he noted that the travel distances from any area in both suites to an egress door and the travel distance between the egress doors and exit doors are all less than 40 m (131 ft 3 in), thereby complying with the Code.

The Applicant also indicated that not only would the safety of the suites be enhanced by the number of exit options, but the fact that these exit routes would lead to different corridors, not just a single public corridor with two exits, would provide a higher degree of occupant safety as well.

In this way, with both suites having access to at least two separate exits, the Applicant concluded by stating the proposed sublet design, including the single exit public corridor, by utilizing the exceptions allowed in Section 3.3, meets the intent of Sentence 3.3.1.3.(9).

5. **Respondent's Position**

The Respondent submitted that the subject public corridors are both considered dead end corridors due to the fact that the south-east exit is served by only one exit stair and the rotunda exit has both exit stairs in the same direction. This would result, they argued, in the Apak Systems office being served by two public corridors, both of which are considered dead end. In their view, Sentence 3.3.1.3.(9) allows a suite that is required to be served more than one egress to have one of those egress routes through a dead end corridor, but not both. As a result, they held that design of the subject public corridors contravened Sentence 3.3.1.3.(9) of the OBC.

6. **Commission Ruling**

It is the decision of the Building Code Commission that the proposed single exit public corridor serving two suites, each having an access to a second exit does not provide sufficiency of compliance with Sentence 3.3.1.3.(9) of the Ontario Building Code.

7. **Reasons**

No compensative features were proposed to the Commission to consider sufficiency of compliance.

RULING

1. **The Applicant**

   Mr. Jim Hallman, Aberdeen Homes, 42 Chartwell Court, Kitchener, Ontario, has applied for a building permit under the *Building Code Act, 1992* to construct low-rise residential condominiums, known as the "Catalina" townhouse project, on Caroline Street, in Waterloo, Ontario.

2. **Description of Construction**

   The Applicant proposes to construct a group of three storey residential condominium buildings. Each building will contain a block of units. While the buildings have a total area of greater than 600 m^2 , the individual units all have a building area less than 600 m^2. The buildings will be of combustible construction. The units will be equipped with a hard-wired, interconnected smoke alarm system.

In certain units, as part of the proposed construction, the Applicant intends to provide a window on the loft level, or third storey, as an alternate means of egress. The purpose of this is so that occupants on the third storey would not have to travel more than one storey to reach an exit. The subject windows would be designed in accordance with OBC Sentence 9.9.9.1.(2). Specifically, they would have an openable area of at least 1 000 mm (3 ft 3in) in height and 550 mm (21 5/8 in) in width. The windows, designed as dormers, would lead to a gradually sloped (12:1) roof area that is to extend 1 125 mm (3 ft 8 in) from the window. This roof area would be 7 m above grade.

The Applicant is also proposing to sprinkler the stairway in the same units in which the third storey egress window is being provided. The sprinkler heads would be installed on the second and third storeys, but not on the ground nor basement levels.

3. **Dispute**

The issue at dispute between the Applicant and Respondent is whether the proposed sprinkler system compensates for the perceived increase in travel distance and thereby provides sufficiency of compliance with Article 9.9.9.1. of the Ontario Building Code. This provision requires that dwelling units with more than one storey must have exit doors positioned in such a way that so that it is not necessary to travel up or down more than one storey to reach a level served by an exit. Sentences (2) and (3) of this Article provide exceptions that, when complied with, allow the exit route to travel more than one storey. Specifically, Sentence (2) permits an increase in the travel distance if an openable window of a certain size is provided, while Sentence (3) allows the same if a balcony is provided.

Provisions of the Ontario Building Code

Article 9.9.9.1. Travel Limit to Exits or Egress Doors

(1) Except as provided in Sentences (2) and (3), every dwelling unit containing more than 1 storey shall have exits or egress doors located so that it shall not be necessary to travel up or down more than 1 storey to reach a level served by

(a)an egress door to a public corridor, enclosed exit stair or exterior passageway, or

(b) an exit doorway not more than 1 500 mm (4 ft 11 in) above adjacent ground level.

(2) Where a dwelling unit is not located above or below another suite, the travel limit from a floor level in the dwelling unit to an exit or egress door is permitted to exceed 1 storey where the floor level is served by an openable window or door.

(a) providing an unobstructed opening of not less than 1 000 mm (3 ft 3 in) in height and 550 mm (21 5/8 in) in width, and

(b) located so that the sill is not more than

i)1 000 mm (3 ft 3 in) above the floor, and

ii)7 m (23 ft) above adjacent ground level.

(3) The travel limit from a floor level in a dwelling unit to an exit or egress door is permitted to exceed 1 storey where that floor level has direct access to a balcony.

4. **Applicant's Position**

The Applicant submitted the proposed installation of a sprinkler heads would provide sufficiency of compliance with Article 9.9.9.1. of the OBC. In his view, the sprinkler coverage would adequately compensate for the increase in travel distance from one storey to two. As he argued, due to the open concept design of the stairs, the entire exit path of travel would be covered by sprinkler protection.

While the Applicant noted that the third storey openable egress window complied with Sentence 9.9.9.1.(2), he indicated that considering the roof design, it was not practical to meet the balcony requirements of Sentence 9.9.9.1.(3) as well. His proposal does include a relatively flat area on the roof immediately below the egress window where occupants could seek refuge in case of a fire. Nevertheless, this area would not be equipped with a guard and does not constitute a balcony, he conceded. It was for this reason that the sprinkler heads were being provided as a compensating measure in order to provide sufficiency of compliance with Sentence 9.9.9.1.(3).

5. **Respondent's Position**

The Respondent submitted that the proposed design does not meet the Code requirements found in Article 9.9.9.1. since, in his view, the egress route to an exit door from the loft level would necessitate travelling down two storeys. While he agreed that the proposed openable window satisfied the criteria found in Sentence (2), he noted that a balcony as per Sentence (3) was also

required. The Respondent indicated that the subject area of refuge does not comply with Sentence 9.9.9.1.(3) since it is proposed to be located on a sloped area of the second storey roof and that no guard rail has been provided.

The Respondent did, however, indicate that he supported the proposed installation of the sprinkler heads in the exit stair as a compensating measure.

6. **Commission Ruling**

It is the decision of the Building Code Commission that the design of the exit from the loft at the third floor level provides sufficiency of compliance with Article 9.9.9.1.(3) of the Building Code provided that;

1) The building is sprinklered throughout or;

2) (a) The entire building exit to grade level, and the second floor bedroom, below the window perch, are protected by sprinklers; and

(b) Interconnected smoke alarms are provided at all floor levels.

7. **Reasons**

It is the opinion of the Commission the sprinklered building or combination of sprinklers to provide exposure protection and early detection provide an acceptable level of safety from fire at the third floor.

For the Respondent

1. **RULING**

   The Applicant

   Mr. Peter Paoli, Project Architect, Pellow & Associates Architects Inc., Toronto, Ontario, has applied for a building permit under the *Building Code Act, 1992* to construct additions onto an existing retail mall known as the Devonshire Mall, 3100 Howard Street, Windsor, Ontario.

2. **Description of Construction**

   The Applicant proposes to renovate the Devonshire Mall by adding two separate additions, totalling 12,259 m^2, to the existing building. The existing noncombustible structure is described as two storeys, with a building area of 76,475 m^2. It is predominantly Group E -Mercantile, however the building also contains Group A1 - Assembly (performing arts), Group A2 - Assembly (general) and Group D - Business occupancies. The building is equipped with a fire alarm, standpipe and hose and sprinkler systems.

The proposed expansion has two phases. Phase one, to be constructed at the south-east corner of the mall, will add a multi-plex theatre facility, containing twelve cinemas. This expansion will also create an outdoor truck loading zone located near the centre of the mall due to the fact that the western wall of the theatre facility is to be set back far enough from the existing building to allow a truck access route. The loading area will be situated at the exit of an existing 6 m wide underground pedestrian egress tunnel. The Applicant proposes to discontinue using the tunnel for exiting purposes, instead it will be used for moving merchandise to certain retail stores within the mall.

The original purpose of the pedestrian exit tunnel was to serve a cluster of retail stores situated in the middle of the mall. These stores form an "island" which is entirely surrounded by a 12 m (9 m wide only on the south end) public corridor that is not fire separated from the floor area. While there are 40 retail stores in the island, just 23 of them have a second exit (only 16 stores are required to do so by Code due to their size) at the rear that connects to a public corridor within the island, which in turn connects to the tunnel entrance located near the middle of the island.

Phase two, to be constructed along much of the west wall of the mall, will add additional retail space facing one of the site's main parking lots. This expansion will cause three of the existing west facing exits to be relocated further west. This relocation will create three areas where the travel distance from the most interior or remote stores to the nearest exit will range from 111 m to 121.5 m in total.

The Applicant is proposing to equip the renovated mall with a smoke management system designed according to NFPA 92B "Smoke Management in Malls, Atria and Large Areas" in which the building will be separated into five smoke protection zones. In the event of a fire,each of the smoke protection zones would operate by forcing smoke to the exterior by two exhaust fans, while providing air to adjacent zones with supply fans. This system would be automatically activated by smoke detection devices located in each zone. Smoke detector actuation would also cause the fire alarm to operate. The system, once constructed, would be tested.

3. **Dispute**

The issue at dispute between the Applicant and Respondent is whether the proposed smoke management system compensates for the elimination of the second means of egress from the 16 retail stores in the island required to have a second exit and the increased travel distance to certain interior areas of the mall, thereby providing sufficiency of compliance with Clause 3.4.2.5.(1)(d) and Subclause 3.4.2.5.(1)(d)(iv) of the Ontario Building Code. These provisions,

while contained in the same Article of the OBC, raise different issues when applied to the proposed expansion phases of the Devonshire Mall.

Clause 3.4.2.5.(1)(d) requires that the travel distance to any part of the floor area of the mall that is served by a non-separated public corridor not exceed 105 m. The phase two relocation of exits at the building's western wall will cause the 105 m limit to be exceeded by a range of 6 m to 16.5 m in three certain areas. The phase one addition also contributes to the travel distance issue for one of the remote areas by relocating an exit at the south-east end of the building farther away.

Subclause 3.4.2.5.(1)(d)(iv) further requires that the rooms or suites which face the subject public corridor and that are required to have a second means of egress only have half of the required egress doorways accessing the corridor. While only 16 stores in the island are required because of their size to have a second means of egress, the termination of the tunnel as a pedestrian exit, as proposed under phase two, means that all occupants from the island area must exit via the 9 m public corridor system in the mall. The second exits provided at the rear of the stores would therefore lead to the interior public corridor of the island and from there to the 9 m wide non-separated public corridors.

4. **Provisions of the Ontario Building Code**

Article 3.4.2.5. Location of Exits

(1) Except as permitted by Sentences (2), (3) and 3.3.2.3.(6), if more than one exit is required from a floor area, the exits shall be located so that the travel distance to at least one exit shall be not more than

(d)105 m (344 ft 6 in) in any floor area, served by a public corridor, in which rooms and suites are not separated from the remainder of the floor area by a fire separation, provided

(iv)not more than one half of the required egress doorways from a room or a suite open into the public corridor if the room or suite is required to have more than one egress doorway.

5. **Applicant's Position**

The Applicant submitted that the proposed smoke management system will provide sufficiency of compliance with the relevant provisions of the OBC since, in their view, it will compensate for the elimination of the second exit for the 16 island stores and the increase in travel distance. The Applicant argued that the approach they were taking in designing their proposed smoke

management system was consistent with the zoned smoke exhaust requirements for interconnected floor spaces found in the OBC. He also noted that similar smoke management systems have been designed and installed in other malls in Ontario, including the Square One Shopping Centre in Mississauga and the Bramalea City Centre in Brampton.

In particular, the Applicant argued that the proposed smoke management system would accomplish two functions. The first would be to provide a way to isolate large areas of the mall to create zones which would control the spread of smoke from contaminating other areas. The Applicant is proposing that the three egress routes from island's interior public corridor would exit into three different smoke control zones. This would assist the 16 stores without a second exit because it would offer a choice of at least two egress routes and would ensure that either exit of any store could access a different smoke control zone. Having the entire occupant load of the island exiting via the mall's public corridors is not a problem in terms of exit capacity, he noted.

The second function the smoke management system would accomplish would be to reduce the travel distance from the remote areas in the interior of the mall to less than 105 m. This would be possible since the structure would be divided into smoke control zones, thereby making the travel distance from any part of the mall to another smoke zone less than 105 m. The Applicant noted, however, that even without a smoke control system, a travel distance which exceeds the required limit by 16 m, adds only 12 seconds more exiting time calculated at a walking pace.

The Applicant offered other advantages of the smoke control system. Specifically, he noted that the smoke detection features, which are not required in shopping centre corridors, will provide early notice of a fire to building staff, occupants and the fire department. The smoke exhaust system will also enhance the safety of the building during an evacuation. Further, he argued that this system is more useful than a concealed tunnel, since most occupants would probably instinctively use the mall's corridor system when exiting. The Applicant also pointed out that the smoke exhaust feature assists during fire fighting activities.

For these reasons, the Applicant concluded that the proposed smoke management systemprovides sufficiency of compliance with the Ontario Building Code.

6. **Respondent's Position**

The Respondent submitted that eliminating the second exit from the 16 island stores and exceeding the travel distance will contravene Clause 3.4.2.5.(1)(d) and Subclause 3.4.2.5.(1)(d)(iv) of the Building Code.

Nevertheless, he noted that he was supportive of the Applicant's proposed smoke control system, however, he indicated that he felt this was beyond his jurisdiction to authorize. The Respondent requested that if the Building Code Commission were to rule that the proposal offered sufficiency of compliance, that they do so on the condition that the system be maintained and tested on an annual basis and that the results be made available to the Chief Building Official or Chief Fire Official of the City of Windsor.

7. **Commission Ruling**

It is the decision of the Building Code Commission that the additions and renovations to Devonshire Mall provides sufficiency of compliance with Clause 3.4.2.5.(i)(d) and Article 3.4.3.2. of the Building Code on the conditions that

i)The intended smoke management system is designed and installed in conformance with NFPA 92B;

ii)Commissioned upon completion of construction to perform as designed; and

iii)Inspected, tested and maintained in accordance with the schedule established in NFPA 92B.

8. **Reasons**

i) The smoke management system is designed to allow more egress time for safe evacuation.

ii) The travel time as a result of the increase in travel distance is estimated to be no more than 15 seconds.

iii) Increased early warning through the installation of smoke detectors in the smoke zones is provided.

iv) The smoke management system is considered a life safety system and required to be inspected and tested according to the NFPA standard.

RULING

1. The Applicant

Mr. Thomas Phillips, Owner, Part Lot 18, Concession 1, brought a dispute to the Building Code Commission regarding the ventilation of the washroom and the fire stopping of a farm building into conformity with the relevant requirements of the of the OBC and the NFBCC at Part Lot 18, Concession 1, Carden Township, Ontario.

2. Description of Construction

The construction in dispute was not described.

<![endif]>

3. Dispute

The issues relating to the technical requirements of the Ontario Building Code were not discussed.

4. Provisions of the Ontario Building Code

Sentence 7.1.7.1.(1) Lighting and Ventilation Requirements

(1) Plumbing fixtures shall not be installed in a room that is not lighted and ventilated in accordance with the appropriate requirements in Parts 3 and 9.

Provisions of the National Farm Building Code of Canada

Sentence 3.1.3.1.(1) Location

(1) Fire stops shall be provided at floor, ceiling and roof levels to cut off all concealed draft openings occurring between storeys and between the top storey and roof space, including spaces filled with batt, loose fill or foamed plastic insulation.

5. Applicant's Position

No arguments regarding technical matters were presented by the Applicant.

6. Respondent's Position

No arguments regarding technical matters were presented by the Respondent.

7. Commission Ruling

It is the decision of the Building Code Commission that the application for a hearing lacks jurisdiction under Section 24 of the Building Code Act to hold a hearing in this matter, as the Applicant is not Aan

applicant for a permit or a holder of a permit or a person to whom an order is given@ within the meaning of s 24(1) of the Act.

The Respondent

RULING

1. **The Applicant**

   Mr. Clare Wamsteeker, Manager, Physical Plant, Brantwood Residential Development Centre, Brantford, Ontario, has received a building permit under the *Building Code Act, 1992* and is currently constructing a group home known as the Nelson Street Group Home, at 430 Nelson Street, Brantford, Ontario.

2. **Description of Construction**

   The Applicant is currently constructing a one storey (with a partial basement), group home with a building area of 288 m^2 (3,099 ft^2) (excluding garage) that is intended to house only 6 residents as well as up to 3 or 4 full time staff members. The building is of combustible construction and is classified as having a Group B, Division 3 (care) occupancy under the 1997 Ontario Building Code. The separations between the basement and ground floor and between the bedrooms within the group home will have a 3/4 hour fire-resistance rating.

The structure will not be equipped with a fire alarm system, but will be supplied with an interconnected smoke detection system and a sprinkler system. The Applicant is proposing that this latter system be designed and installed in accordance with the requirements of NFPA 13R, "Standard for the Installation of Sprinkler Systems in Residential Occupancies up to and Including Four Stories in Height."

3. **Dispute**

The issue at dispute between the Applicant and Respondent is whether a sprinkler system constructed to the NFPA 13R standard achieves sufficiency of compliance with Article 3.2.2.41. and Sentences 3.2.5.13.(1) and 3.2.5.13.(2) of the Ontario Building Code. Article 3.2.2.41. requires that a B3 occupancy must be sprinklered even though it may be of combustible construction. The dispute therefore centres on the type of sprinkler system that is required.

The NFPA 13R standard stipulates that a sprinkler system be designed and installed for all occupied rooms. The NFPA 13 standard, however, goes further by also requiring sprinklering in unoccupied areas such as closets and concealed spaces such as attics. Sentence 3.2.5.13.(1) states that a required sprinkler system must meet NFPA 13, whereas Sentence 3.2.5.13.(2), provides an exception to Sentence (1) by allowing low rise (four stories or less) residential occupancies to comply with the more relaxed sprinkler standards found in NFPA 13R.

If the subject group home, as a low rise structure intended for a maximum of only 10 people, could also be considered a residential occupancy according to the OBC, then the NFPA 13R standard would be an appropriate requirement for sprinklering.

4. **Provisions of the Ontario Building Code**

Article 3.2.2.41. Group B Division 2 or Division 3, One Storey, Sprinklered

(1) A building classified as Group B, Division 2 or Division 3 is permitted to be of combustible construction or noncombustible construction used singly or in combination, provided

(a) except as permitted by Sentence 3.2.2.7.(1), the building is sprinklered,

(b) it is not more than 1 storey in building height, and

(c) it has a building area not more than 500 m2 (5,380 ft2).

Sentence 3.2.5.13. Automatic Sprinkler Systems

(1) Except as permitted by Sentences (2), (3) and (4), an automatic sprinkler system shall be designated, constructed, installed and tested in conformance with NFPA 13, "Standard for the Installation of Sprinkler Systems".

(2) Instead of the requirements of Sentence(1), NFPA 13R, "Standard for the Installation of Sprinkler Systems in Residential Occupancies up to and Including Four Stories in Height", is permitted to be used for the design, construction, installation and testing of an automatic sprinkler system installed in a building of residential occupancy that is not more than 4 storeys in building height.

5. **Applicant's Position**

At the outset the Applicant indicated that he had recently been to the Building Code Commission representing a project that was very similar to the one at hand, and since the dispute centred on the same issue he would be making similar arguments as before.

The Applicant submitted that the group home currently under construction should be considered as residential facility under the OBC, thereby allowing the proposed NFPA 13R conforming sprinkler system to be installed. The Applicant argued that the subject group home physically resembles a house from both the exterior, with its small size, and interior, with its homelike floor plans. He noted that the construction techniques are also residential in nature. Moreover, the proposed group home will function like every other family home with the staff acting as parents and residents as children and siblings. In his view, it was not the intent of the 1997 OBC to require the more onerous NFPA 13 sprinkler standard for such small buildings of residential character and function. He suggested that smaller facilities (asmeasured by their floor area or occupant load) in the B3 classification be allowed to comply with NFPA 13R.

Considering that all occupied rooms would be sprinklered (according to NFPA 13R), that fire separations would be provided between floors and bedrooms, that interconnected smoke detectors would be installed, and that evacuation would be quick, the Applicant stated that the life safety of the residents would be adequately protected without relying upon the more rigorous NFPA 13 requirements. Besides, as he argued, the principal difference in terms of protection offered by either sprinkler systems if installed in a such a building is that an NFPA 13 system would protect both occupants and the building, whereas a NFPA 13R system would only protect the occupants. The protection of property, in the Applicant's view, is not worth the additional

expense. As he noted, by employing the NFPA 13 sprinkler standard, the construction costs of these already expensive homes would increase.

The Applicant also pointed out that historically there has been some confusion regarding the appropriate Building Code classification in which to determine construction standards for groups homes. He indicated that this uncertainty continued to the present 1997 version of the OBC. He stated that many like group homes were being constructed across the province with some conforming to NFPA 13, while many others were allowed to use NFPA 13R sprinkler systems. In fact, several recent similar projects in a neighbouring municipalities were allowed to proceed based on NFPA 13R proposed systems.

Lastly, the Applicant indicated that many safety and accessibility features had been included in the subject home, with some of these being beyond the minimum standards required in the Code.

6. **Respondent's Position**

The Respondent submitted that the subject care home is not a residential facility and thus the sprinkler system should be designed and installed according to NFPA 13. As he noted, the 1997 OBC allows a care facility to be considered as having a Group C (residential) major occupancy using the exemption found in Article 3.1.2.5. The building at hand, he argued, did not meet the criteria for this exemption however, since more than two people would require assistance to evacuate in an emergency. Therefore, in the Respondent's view, a care occupancy is not by definition a residential occupancy. Accordingly, a building classified as having a care occupancy does not qualify for any of the exemptions in Article 3.2.5.13. and instead must conform with NFPA 13 standards for sprinkler design and installation.

The Respondent did, however, offer that the Applicant's proposal to utilize the NFPA 13R sprinkler system would provide reasonable protection. Nevertheless, he indicated that he felt it was beyond his authority to permit an NFPA 13R sprinkler system.

7. **Commission Ruling**

It is the decision of the Building Code Commission that a sprinkler system constructed to NFPA 13R provides sufficiency of compliance with 3.2.5.13.(1) and (2) in the B3 occupancy constructed to Article 3.2.2.41 of the Building Code provided that;

i) bedroom fire separations having a 3/4 hour fire resistance rating are provided in accordance with Ontario Building Code requirements,

and

ii) manual initiating devices are in a location easily accessible to supervisory staff to initiate the operation of the interconnected smoke alarms.

8. **Reasons**

i) The single storey building is small in size, with limited occupant load of 6 residents plus full time supervisory staff.

ii) The additional compartmentation and early warning features provide an additional level of safety from fire.

9. **Recommendation**

As these are the second and third cases of a smiliar nature brought before the Commission, the Commission recommends that a code change be considered to review the conditions under which NFPA 13R sprinklers may be used in a B3 occupancy.

The Respondent

RULING

1. **The Applicant**

   Mr. Clare Wamsteeker, Manager, Physical Plant, Brantwood Residential Development Centre, Brantford, Ontario, has received a building permit under the *Building Code Act, 1992* and is currently constructing a group home known as the Nelson Street Group Home, at 346 Nelson Street, Brantford, Ontario.

2. **Description of Construction**

   The Applicant is currently constructing a one storey (with a partial basement), group home with a building area of 223 m^2 (2,400 ft^2) (excluding garage) that is intended to house only 6 residents as well as up to 3 or 4 full time staff members. The building is of combustible construction and is classified as having a Group B, Division 3 (care) occupancy under the 1997 Ontario Building Code. The separations between the basement and ground floor and between the bedrooms within the group home will have a 3/4 hour fire-resistance rating.

The structure will not be equipped with a fire alarm system, but will be supplied with an interconnected smoke detection system and a sprinkler system. The Applicant is proposing that this latter system be designed and installed in accordance with the requirements of NFPA 13R, "Standard for the Installation of Sprinkler Systems in Residential Occupancies up to and Including Four Stories in Height."

3. **Dispute**

The issue at dispute between the Applicant and Respondent is whether a sprinkler system constructed to the NFPA 13R standard achieves sufficiency of compliance with Article 3.2.2.41. and Sentences 3.2.5.13.(1) and 3.2.5.13.(2) of the Ontario Building Code. Article 3.2.2.41. requires that a B3 occupancy must be sprinklered even though it may be of combustible construction. The dispute therefore centres on the type of sprinkler system that is required.

The NFPA 13R standard stipulates that a sprinkler system be designed and installed for all occupied rooms. The NFPA 13 standard, however, goes further by also requiring sprinklering in unoccupied areas such as closets and concealed spaces such as attics. Sentence 3.2.5.13.(1) states that a required sprinkler system must meet NFPA 13, whereas Sentence 3.2.5.13.(2), provides an exception to Sentence (1) by allowing low rise (four stories or less) residential occupancies to comply with the more relaxed sprinkler standards found in NFPA 13R.

If the subject group home, as a low rise structure intended for a maximum of only 10 people, could also be considered a residential occupancy according to the OBC, then the NFPA 13R standard would be an appropriate requirement for sprinklering.

4. **Provisions of the Ontario Building Code**

Article 3.2.2.41. Group B Division 2 or Division 3, One Storey, Sprinklered

(1) A building classified as Group B, Division 2 or Division 3 is permitted to be of combustible construction or noncombustible construction used singly or in combination, provided

(a) except as permitted by Sentence 3.2.2.7.(1), the building is sprinklered,

(b) it is not more than 1 storey in building height, and

(c) it has a building area not more than 500 m2 (5,380 ft2).

Sentence 3.2.5.13. Automatic Sprinkler Systems

(1) Except as permitted by Sentences (2), (3) and (4), an automatic sprinkler system shall be designated, constructed, installed and tested in conformance with NFPA 13, "Standard for the Installation of Sprinkler Systems".

(2) Instead of the requirements of Sentence(1), NFPA 13R, "Standard for the Installation of Sprinkler Systems in Residential Occupancies up to and Including Four Stories in Height", is permitted to be used for the design, construction, installation and testing of an automatic sprinkler system installed in a building of residential occupancy that is not more than 4 storeys in building height.

5. **Applicant's Position**

At the outset the Applicant indicated that he had recently been to the Building Code Commission representing a project that was very similar to the one at hand, and since the dispute centred on the same issue he would be making similar arguments as before.

The Applicant submitted that the group home currently under construction should be considered as residential facility under the OBC, thereby allowing the proposed NFPA 13R conforming sprinkler system to be installed. The Applicant argued that the subject group home physically resembles a house from both the exterior, with its small size, and interior, with its homelike floor plans. He noted that the construction techniques are also residential in nature. Moreover, the proposed group home will function like every other family home with the staff acting as parents and residents as children and siblings. In his view, it was not the intent of the 1997 OBC to require the more onerous NFPA 13 sprinkler standard for such small buildings of residential character and function. He suggested that smaller facilities (asmeasured by their floor area or occupant load) in the B3 classification be allowed to comply with NFPA 13R.

Considering that all occupied rooms would be sprinklered (according to NFPA 13R), that fire separations would be provided between floors and bedrooms, that interconnected smoke detectors would be installed, and that evacuation would be quick, the Applicant stated that the life safety of the residents would be adequately protected without relying upon the more rigorous NFPA 13 requirements. Besides, as he argued, the principal difference in terms of protection offered by either sprinkler systems if installed in a such a building is that an NFPA 13 system would protect both occupants and the building, whereas a NFPA 13R system would only protect the occupants. The protection of property, in the Applicant's view, is not worth the additional

expense. As he noted, by employing the NFPA 13 sprinkler standard, the construction costs of these already expensive homes would increase.

The Applicant also pointed out that historically there has been some confusion regarding the appropriate Building Code classification in which to determine construction standards for groups homes. He indicated that this uncertainty continued to the present 1997 version of the OBC. He stated that many like group homes were being constructed across the province with some conforming to NFPA 13, while many others were allowed to use NFPA 13R sprinkler systems. In fact, several recent similar projects in a neighbouring municipalities were allowed to proceed based on NFPA 13R proposed systems.

Lastly, the Applicant indicated that many safety and accessibility features had been included in the subject home, with some of these being beyond the minimum standards required in the Code.

6. **Respondent's Position**

The Respondent submitted that the subject care home is not a residential facility and thus the sprinkler system should be designed and installed according to NFPA 13. As he noted, the 1997 OBC allows a care facility to be considered as having a Group C (residential) major occupancy using the exemption found in Article 3.1.2.5. The building at hand, he argued, did not meet the criteria for this exemption however, since more than two people would require assistance to evacuate in an emergency. Therefore, in the Respondent's view, a care occupancy is not by definition a residential occupancy. Accordingly, a building classified as having a care occupancy does not qualify for any of the exemptions in Article 3.2.5.13. and instead must conform with NFPA 13 standards for sprinkler design and installation.

The Respondent did, however, offer that the Applicant's proposal to utilize the NFPA 13R sprinkler system would provide reasonable provide. Nevertheless, he indicated that he felt it was beyond his authority to permit the proposed sprinkler system.

7. **Commission Ruling**

It is the decision of the Building Code Commission that a sprinkler system constructed to NFPA 13R provides sufficiency of compliance with 3.2.5.13.(1) and (2) in the B3 occupancy constructed to Article 3.2.2.41 of the Building Code provided that;

i) bedroom fire separations having a 3/4 hour fire resistance rating are provided in accordance with Ontario Building Code requirements,

and

ii) manual initiating devices are in a location easily accessible to supervisory staff to initiate the operation of the interconnected smoke alarms.

8. **Reasons**

i) The single storey building is small in size, with limited occupant load of 6 residents plus full time supervisory staff.

ii) The additional compartmentation and early warning features provide an additional level of safety from fire.

9. **Recommendation**

As these are the second and third cases of a smiliar nature brought before the Commission, the Commission recommends that a code change be considered to review the conditions under which NFPA 13R sprinklers may be used in a B3 occupancy. RULING

1. **The Applicant**

   Mr. Satya Saha, Project Manager, C.I.B.C. Development Corporation has received an order to comply under the *Building Code Act, 1992* to remedy two doors at 1 City Centre Drive, Unit 105, Mississauga, Ontario.

2. **Description of Construction**

   The Applicant recently renovated a ground floor C.I.B.C. branch tenancy located within a

   17 storey building, classified as having a Group D - business occupancy. The structure has a building area of approximately 2,045 m^2 (22,000 ft^2). The building is of noncombustible construction and is equipped with sprinkler, standpipe and hose, and fire alarm systems.

   Part of the renovation included making the two main entry doors at the C.I.B.C. tenancy barrier-free for disabled access. This involved replacing the existing sets of doors (both swing doors within a set were 710 mm (28 in) wide) with a new 915 mm (36 in) glazed entry swing door with

a 505 mm (20 in) wide hinged side light. The previous door configuration, with individual doors only 710 mm wide, meant that barrier-free access was not possible. The new design has a 915 mm wide door and a push-plate activated opening device, thus making disabled access possible.

Public access to the bank is from the building's ground floor lobby through the two main entry doors. The bank has a third exit, but it accessible only by bank staff. One of the exit stairs for the office tower above the bank branch does not exit directly to the exterior of the building. Instead, the subject exit stairs exit through the bank and then through the lobby of the building to the exterior. There are six exits to the exterior from the lobby.

The hardware for the subject main entry doors is the Kawneer Dor-o-matic 1990 Concealed Rod exit device. It contains a latching rod mechanism contained in the door stile, which inserts into the door threshold and the transom/header. This latching mechanism is de-activated during banking hours to allow the barrier-free access push-plates to operate. The door returns automatically to a closed position after each use.

3. **Dispute**

The issue at dispute between the Applicant and Respondent is whether the entrance new doors, as installed, provide sufficiency of compliance with Article 3.1.8.3. of the Ontario Building Code. Article 3.1.8.3. requires all swing-type doors, with certain exceptions, in a fire separation to be equipped with a positive latching mechanism that holds a door when shut in a closed position. While the two main entry doors contain positive latching mechanisms to maintain a closed position after opening, these doors are operated by the Applicant in such a manner that the devices are de-activated during business hours.

4. **Provisions of the Ontario Building Code**

Article 3.1.8.13. Door Latches

(1) Except as permitted by Article 3.3.3.5., a swing-type door in a fire separation shall be equipped with a positive latching mechanism designed to hold the door in the closed position after each use.

5. **Applicant's Position**

The Applicant submitted that the newly installed doors, including the latching mechanism, provides sufficiency of compliance with Article 3.1.8.13. He argued, the subject doors do indeed

have a positive latching mechanism as required by the Code, however, the doors are operated in such a way that the latching device is not employed during certain times. As he indicated, the rationale for using the doors in this fashion was to improve the barrier-free accessibility. This, after all, was the main reason why the original doors were replaced. By not having the latching pin engaged during business hours, this allows the push-plates located both inside and outside of the bank to open the doors when entering and leaving the bank.

The Applicant also noted other features of the door hardware which were recently added to improve accessibility. None of these features are in dispute.

The Applicant indicated that the subject doors are equipped with a self-closing devices. The doors and side light panels, he also noted, have been fitted with full height tamper proof astragal plate which provides a cover for the air gap between the two leaves, thus providing a better seal and therefore maintaining the fire separation.

With respect to the fire separation aspect of this dispute, the Applicant acknowledged that in the event of a fire the opening and closing of the subject two main exit doors in the bank branch could be viewed by some as providing a weak point in the fire separation. Nevertheless, citing OBC Appendix A-3.1.8.1.(1)(b) Barrier to Control Smoke Spread, he argued that the intent of the Code with respect to fire separations, including the one in which the two entry doors are located, is to control the spread of smoke until the sprinkler system activates. If the pressure differential caused by smoke and heat is large enough to push open these doors, in his view, the sprinkler system would have activated by then. In turn, the actuation of the sprinkler system would begin to bring the fire under control thereby reducing the pressure differential and making the holding function of the latching mechanism less critical.

In an effort to make the doors more resistant to a build up of pressure differential in a fire situation, the Applicant offered to increase the tension on the door closing device.

Lastly, the Applicant noted that the Respondent did not object to the subject doors on the original permit application. He indicated that it was only brought to his attention six months after installation had occurred.

6. **Respondent's Position**

The Respondent submitted that although the doors may have positive latching mechanism, since that device is not engaged during business hours, the operation of these doors does not comply

with the Code, specifically Article 3.1.18.3. By using the doors in such a manner, the Applicant, they argued, is allowing the fire separation to be penetrated. The Respondent expressed concern that because one of the main exit stairs of the 16 storey building above leads into the bank, and relies upon the subject doors for exit into the lobby, this would mean that the lobby and the adjacent occupancies would not be provided with an appropriate fire separation. In their view, the doors' latching mechanism should be engaged at all times.

7. **Commission Ruling**

It is the decision of the Building Code Commission that the door installations in question do not comply with Article 3.1.8.13.

8. **Reasons**

i) The latching mechanisms are disengaged during business hours.

ii) There was no empirical evidence presented to show that the existing automatic closing devices would maintain the integrity of the smoke/fire separation during a fire emergency.

Sasha Milenov Architect
Toronto, Ontario
For the Applicant

RULING

1. **The Applicant**

   Mr. Jaswant Dass, Owner, Jaswant Dass in Trust, Toronto, Ontario, has received a building permit under the *Building Code Act, 1992* to construct interior retail units in a one storey mall known as the Woodbine Market Centre at 30 Vice Regent Blvd., Toronto, Ontario.

2. **Description of Construction**

   The Applicant has recently constructed interior booths within a one storey retail plaza structure classified as having a Group E - Mercantile occupancy, with a building area of 4,073 m^2 (43,834.63 ft^2). The building is a combination of combustible and noncombustible construction. It is equipped with a fire alarm system, a standpipe and hose system, and a sprinkler system.

   The subject shopping mall contains several hundred small retail units ranging in size from 6.5 m^2 to 18.5 m^2. The units are separated by 3 m high combustible partitions that extend roughly half way to the 6 m high ceiling. The larger retail tenants as well as some of the smaller ones located near the building's perimeter are provided with two exits from their units, one to the exterior and one to the 3 m wide interior corridors. Many of the smaller tenants in the interior of the building have only one means of exit leading to the interior corridor.

   At the "booth fronts" of all units, where they face the mall's interior corridors, the Applicant is proposing to install foldable horizontally sliding plastic and steel partitions that are manufactured

by Dynaflair Corporation of Canada. While the movable partitions are not provided with swing-type egress doors, they are equipped with a "bi-part" folding door.

3. **Dispute**

The issue at dispute between the Applicant and Respondent is whether the proposed folding wall partitions, which are to be located in the only exit for many of the mall's retail units, provides sufficiency of compliance with Sentence 3.3.1.11.(3) of the Ontario Building Code. This provision allows an exemption regarding the requirement to provide a door that swings open in the direction of travel on the condition that the subject non-swinging door is not located in the only means of egress. For many of the smaller, interior units within the mall, the bi-part door is their only means of egress, if the folding wall is extended across the front of the booth.

4. **Provisions of the Building Code**

Sentence 3.3.1.11. Sliding Doors

(3) Movable partitions used to separate a public corridor from an adjacent business and personal services occupancy or a mercantile occupancy need not conform to Sentence (1) and Sentences 3.3.1.10.(1) and (2) provided the partitions are not located in the only means of egress. (See Appendix A.)

5. **Applicant's Position**

The Applicant submitted that the proposed folding doors provide sufficiency of compliance with Sentence 3.3.1.11.(3) of the OBC. He argued that the subject doors would be appropriate in an emergency or panic situation when the wall is extended across the booth front since the latching mechanism, employing a thumb turn device, is quite simple to operate and the individual tenants would be familiar with their operation. In fact, keys are not necessary for these doors since the entire wall can be moved and locked in place. Nevertheless, as the Applicant indicated, when the wall is fully folded back, as it is during normal business hours which is when most tenants and shoppers are in the units, the entire booth front, open to the corridor, can act as the exit.

In addition, the Applicant argued that since the individual units are small and most often occupied by the actual tenants themselves, this means that any fire would be quickly noticed and those in the retail areas would be familiar with the building and its egress routes.

Lastly, the Applicant indicated that since the structure is equipped with a fire alarm system, a standpipe and hose system and a sprinkler system, the building is quite safe. For these reasons the Applicant believed that sufficiency of compliance with Sentence 3.3.1.11.(3) was achieved.

6. **Respondent's Position**

The Respondent submitted that Sentence 3.3.1.11.(3) of the OBC clearly allows the door swing exception if the non-swing door is not located in the only means of egress. As he noted, in the case of many of the smaller tenancies, the folding egress doors, as part of the larger movable wall partitions, are the only means of egress. In his view, this clearly does not comply with the Code which, as the Respondent indicated, requires that egress doors swing in the direction of travel.

7. **Commission Ruling**

It is the decision of the Building Code Commission that the moveable wall partitions, asbooth fronts, as the only means of egress provides sufficiency of compliance with 3.3.1.11.(3) of the Building Code on the condition that;

a) the booth fronts do not exceed 5 m in length, and,

b) and the total booth floor area is no greater than 25 m^2.

8. **Reasons**

1) The area of the booth is small and limited in occupant load.

2) The screens will be closed only during non-business operations.

APPEARANCES
Ms. Karen Schad, Director
Carp Ridge Community School
Carp, Ontario
Applicant

RULING

1. The Applicant

Mr. Francis Lepine, Developer, El-Pine Homes, Ottawa, Ontario, has received a building permit under the Building Code Act, 1992 to construct multiple three storey residential condominium buildings at Robson Court, Kanata, Ontario.

2. Description of Construction

The Applicant is currently constructing multiple three storey (not including the basement level) condominiums buildings, classified as having a Group - C occupancy, each with a building area of 578 m2 (6,222 ft2). The subject building blocks each contain residential units, some of which are split level. The basement level for each block is a common underground parking area for the units above. The basements are constructed of noncombustible construction, whereas the three storeys above are combustible construction. The buildings are equipped with a fire alarm system.

Each building block will be equipped with an elevator serving the basement and the first and second storeys. On the basement and ground floor levels the proposed elevator shaft would open into an enclosed vestibule. On the second floor the elevator would open into a public corridor. The Applicant, however, is proposing to construct the ground floor elevator lobby without an enclosure so that the lift would open into a dead-end public corridor. This is not an issue on the second floor corridor because with exit stairs at the rear it is not a dead-end corridor.

<![endif]>

3. Dispute

The issue at dispute between the Applicant and Respondent is whether the proposed ground floor elevator vestibules, constructed without enclosure, that opens into a dead-end public corridors provides sufficiency of compliance with Sentence 9.9.7.2.(2) of the Ontario Building Code. This provision permits a dead-end corridor in a residential occupancy with conditions that only suite doors can open into the public corridor and that no more than two doors must be passed to access the nearest exit. In the subject building blocks the Applicant is proposing that the elevator shaft open directly into the dead-end public corridor.

4. Provisions of the Ontario Building Code

Sentence 9.9.7.2. Dead End Corridors

(2) Dead-end public corridors in residential occupancies and business and personal services occupancies shall contain only suite door openings arranged so that not more than 2 such doors have to be passed to reach the nearest exit. The area of wired glass in such doors shall not exceed 645 cm2 (100 in2).

5. Applicant's Position

The Applicant submitted that the proposed elevator vestibule design opening into the dead-end public corridor provides sufficiency of compliance with Sentence 9.9.7.2.(2). He argued that such a configuration would be permissible if the building had been reviewed under Part 3 of the OBC. In Part 9, under which the building was reviewed, a dead-end corridor must contain only residential suite doors arranged in such a fashion that no more than two doors can be passed while exiting. Part 3, on the other hand, the Applicant noted, permits dead-end corridors as long as six metres as long as they do not pass rooms that contain fuel fired appliances or are considered hazardous for other reasons.

The Applicant also noted that there are only two residential suite doors on the ground floor, thereby not exceeding the allowed maximum of suite doors to pass in Sentence 9.9.7.2.(2).

As well, the Applicant argued that the elimination of the vestibule enclosure on the ground floor would make the access to the elevator and the corridor itself more consistent with the second floor corridor.

6. Respondent's Position

The Respondent submitted that Sentence 9.9.7.2.(2) permits only residential suite doors to open into a dead-end public corridor. An unenclosed elevator vestibule is not permitted according to this provision of the OBC. As such, they do not feel the proposal provides sufficiency of compliance with Sentence 9.9.7.2.(2).

7. Commission Ruling

It is the decision of the Building Code Commission that the proposed design to open the elevator at the ground floor directly into a dead end corridor provides sufficiency of compliance with Sentence 9.9.7.2.(2) of the Building Code.

8. Reasons

i. The proposed design improves the integrity of the stairwell enclosure by removing the elevator from the enclosure at the first floor level.
ii. The building has only two suites at the first floor served by the dead end corridor, and each suite is served by a second and separate exit as permitted in Sentence 9.9.7.2.1.(b).
iii. This building is equipped with a fire alarm system.

iv. In the opinion of the Building Code Commission the proposal does not reduce the level of safety from fire in this building.

RULING

1. **The Applicant**

   Mr. Ted Van, Project Manager, Goldlist Properties Inc., 65 Overlea Blvd., Toronto, Ontario, has applied for a building permit under the *Building Code Act, 1992* to construct a 27 storey, residential condominium building known as Allegro at Opera Place at 909 Bay Street, Toronto, Ontario.

2. **Description of Construction**

   The Applicant is proposing to construct a new 27 storey, Group C - Residential condominium structure, with a building area of 1,169 m^2. The building is to be constructed of noncombustible construction, and will be equipped with a fire alarm system, a standpipe and hose system, but not a sprinkler system.

   The exterior balconies of the subject building are proposed to be built with a curb or upstand at the threshold of the doorway. The balconies are not intended as areas of refuge, therefore the Applicant does not intend to make them barrier-free.

3. **Dispute**

The issue at dispute between the Applicant and Respondent is whether the proposed dwelling unit balconies, which are not intended as areas of refuge, are required to be barrier-free when considering Sentence 3.8.2.1.(3) of the Ontario Building Code. In other words, the issue centres on whether this provision applies only to balconies that are built specifically to meet the barrier-free path of travel fire protection requirements of the 1997 OBC, in particular Article 3.3.1.7., or whether it applies to all dwelling unit balconies, including those in the subject building. If the latter is found to be the interpretation of the Code, modifications to the balconies would be necessary.

4. **Provisions of the Building Code**

Article 3.3.1.7. Protection on Floor Areas With a Barrier-Free Path of Travel

(1) Except as provided in sentences (2) and (3), every floor area above or below the first storey that has a barrier-free path of travel shall

(a) be served by an elevator

(i) conforming to Sentences 3.2.6.9.(4) to (6),

(ii) protected against fire in conformance with Clauses 3.2.6.9.(3)(b) or (c), and

(iii) in a building over 3 storeys in building height, protected against smoke movement so that the hoistway will not contain more than 1% by volume of contaminated air from a fire floor during a period of 2 h after the start of a fire, assuming an outdoor temperature equal to the January design temperature on a 2.5% basis determined in conformance with Subsection 2.5.1., or

(b) be divided into at least 2 zones by fire separations conforming to Sentences (4), (5) and (6) so that

(i) persons with physical disabilities can be accommodated in each zone,

(ii) the travel distance from any point in one zone to a doorway leading to another zone shall be not more than the value for travel distance permitted by Sentence 3.4.2.5.(1) for the occupancy classification of the zone, and

(iii) a barrier-free path of travel is provided to an exit.

(2) In residential occupancies, the requirements of Sentence (1) are waived if a balcony conforming to Sentence (7) is provided for each suite, except for suites on the storey containing the barrier-free entrance described in Article 3.8.1.2.

(3) The requirements of Sentences (1) and (2) are waived when the building is sprinklered.

Sentence 3.8.2.1.(3)Areas requiring Barrier-Free Path of Travel

(3) Where a balcony is provided in a dwelling unit, access shall be provided to the balcony

(a) by a doorway with a clear width of not less than 800 mm (2 ft 7 in) when the door is in the open position, and

such that no projection above the walking surface is more than 13 mm (« in).

5. **Applicant's Position**

The Applicant submitted that Sentence 3.8.2.1.(3) of the OBC is not applicable to all residential unit balconies, it is only meant for balconies which are designed with the intention of satisfying the requirements of Article 3.3.1.7.

In his view, Sentence 3.8.2.1.(3) and Article 3.3.1.7. should be considered together, not in isolation, since the two provisions are integrally linked. As the Applicant noted, Article 3.3.1.7. mandates a requirement for certain fire protection measures on floor areas with a barrier-free path of travel. This provision, however, offers several compliance options. These are; to provide a firefighters' elevator [3.3.1.7.(1)(a)], to subdivide the floor area with fire separations [3.3.1.7.(1)(b), to provide a balcony that can act as a fire refuge [3.3.1.7.(2)], or to sprinkler the building [3.3.1.7.(3)]. Sentence 3.8.2.1.(3), the Applicant argued, simply followsfrom the compliance choice found in Sentence 3.3.1.7.(2) and sets out a specific standard detailing the construction of a balcony that has been designed as a method of conforming to the general requirement for fire protection on floor areas with a barrier-free path travel. He stressed that Sentence 3.8.2.1.(3) should not be viewed as a stand alone requirement dictating the design of balconies that are not intended as barrier-free areas of refuge.

The Applicant argued that his interpretation of Sentence 3.8.2.1.(3) and Article 3.3.1.7. are based on the historical development of these particular Code provisions in both the National Building

Code (NBC) and the OBC. He presented an historical overview of the development of these provisions.

By way of background, the Applicant discussed the lack of clarity in the 1990 versions of the NBC and OBC that surrounded the issue of accessibility to balconies that were intended as areas of refuge. The problem, as the Applicant described it, was that the subject balconies were built large enough to accommodate wheelchairs, but that the curb constructed at the threshold to the balcony did not allow for wheelchair access. The 1995 NBC attempted to address this by modifying its Clause 3.3.1.7.(5)(a) to stipulate that a balcony had to provide "direct barrier-free access from the suite or floor area". While not providing precise construction standards, the Applicant noted that this provision did require that the balconies referred to in that Article had to be accessible.

When Ontario modified its Building Code in 1997, it chose not to amend Article 3.3.1.7., instead, partly due to its attempt to consolidate the barrier-free requirements, Ontario chose to modify Article 3.8.2.1. (found within Section 3.8, Barrier-Free Design) by adding a new Sentence (3). This Sentence also required access to the balcony and, in fact, went further by including precise construction requirements. The obvious intent behind this revision to the OBC, the Applicant argued, was to follow the NBC lead in developing provisions to help clarify Article 3.3.1.7. regarding balcony access, the main difference being that the OBC clarification change was made specifically to the section regarding barrier-free standards. Unfortunately, the Applicant indicated, the OBC change did not cross-reference Article 3.3.1.7. as the NBC change had done.

The Applicant also presented evidence in the form of a statement from the Chair of the 1997 Barrier-Free OBC Committee indicating that the members on that panel did not anticipate that their discussions and considerations of Sentence 3.8.2.1.(3) were intended to apply to balconies that were not designed as areas of refuge.

The Applicant also argued that it was not the intention to amend the OBC to require universal balcony accessibility because a new change of that magnitude would have gone through an extensive consultation process. This issue had no consultation, and was not discovered by Code users until after the 1997 OBC came into effect.

The Applicant asserted that many practical problems would arise if the Respondent's interpretation concerning barrier-free accessibility to all balconies was correct. Specifically, without a curb at the threshold water penetration would likely occur. In turn, this wouldcause

difficulties for condominium owners/tenants and would probably result in lawsuits and/or claims with designers, builders and the New Home Warranty Program. Design solutions to deal with water penetration are problematic and expensive, he indicated.

The 13 mm (1/2 in) allowable difference between interior and exterior grades causes other problems too. Floor finishes, for example, must be restricted to thin materials only, otherwise the 13 mm restriction will be exceeded. As well, considering usual construction tolerances, the Applicant noted that a 13 mm variation between grades is difficult to achieve. Having no sizeable threshold also causes difficulties regarding installation of baseboard heating elements. Finally, if all balconies must meet the standards for accessibility, the Applicant pointed out that smaller balconies would not be possible because they could not accommodate a wheelchair, although many such balconies have been designed and built in Ontario.

Lastly, the Applicant concluded by stating that the Respondent's position was based on a much too literal reading of the OBC. This has led to an interpretation of the Code that ignores the intent behind the said provisions. For the reasons stated above, he believes that the intent of OBC 3.3.1.7. and 3.8.2.1.(3) does not require all balconies, including those in dispute, to be barrier-free, only those that intended as areas of refuge.

6. **Respondent's Position**

The Respondent submitted that all balconies are required to be barrier-free. In his view, the Code is quite clear. Sentence 3.8.2.1.(3) explicitly states that dwelling units that have balconies must have a doorway with a clear width of at least 800 mm (2 ft, 7 in), and that no projection above the walking surface be more than 13 mm. In other words, there can be no curb or upstand at the threshold. He argued that, as an enforcement official, he must rely on the plain meaning of the provisions as set down in the OBC. As a result, he believes that Sentence 3.8.2.1.(3) requires the subject balconies to be barrier-free.

7. **Commission Ruling**

It is the decision of the Building Code Commission that the requirements of Sentence 3.8.2.1.(3) of the Building Code apply only with respect to balconies provided to satisfy Sentence 3.3.1.7.(7) of the Building Code.

8. **Reasons**

1) The introduction of the requirements in Sentence 3.8.2.1.(3) for balcony access was based on the 1995 NBC change series which clearly limits the application of balcony access to Article 3.3.1.7., "Protection on Floor Areas With a Barrier-Free Path of Travel."

2) The application of Sentence 3.8.2.1.(3) to all balconies would be contradictory to Clause 3.8.2.1.(2)(k) which exempts barrier free access within suites of residential occupancy.

3) Editorial changes to Sentence 3.8.2.1.(1) and Sentence 3.3.1.7.(7) are required for clarification purposes.

4) The Commission reviewed Appendix A to the Building Code under Sentence 3.8.2.1.(2) for direction on the intent of the code, which is consistent with the decision.

5) It is the assessment of the Building Code Commission that the intent of the Building Code in reviewing all evidence presented is that Sentence 3.8.2.1.(3) applies only to balconies used as required in Article 3.3.1.7.

RULING

1. **The Applicant**

   Mr. Tim Gorley, Project Manager, Page + Steele Architects Planners, 95 St. Clair Avenue West, Toronto, Ontario, has applied for a building permit under the *Building Code Act, 1992* to construct a 12 storey, residential condominium building at 550 Queens Quay West, Toronto, Ontario.

2. **Description of Construction**

   The Applicant is proposing to construct a new 12 storey, Group C - Residential condominium structure, with a building area of 2,148 m^2. The building is to be constructed of noncombustible construction, and will be equipped with a fire alarm system, a standpipe and hose system, but not a sprinkler system.

   The exterior balconies of the subject building are proposed to be built with a curb or upstand at the threshold of the doorway. The balconies are not intended as areas of refuge, therefore the Applicant does not intend to make them barrier-free.

3. **Dispute**

The issue at dispute between the Applicant and Respondent is whether the proposed dwelling unit balconies, which are not intended as areas of refuge, are required to be barrier-free when considering Sentence 3.8.2.1.(3) of the Ontario Building Code. In other words, the issue centres on whether this provision applies only to balconies that are built specifically to meet the barrier-free path of travel fire protection requirements of the 1997 OBC, in particular Article 3.3.1.7., or whether it applies to all dwelling unit balconies, including those in the subject building. If the latter is found to be the interpretation of the Code, modifications to the balconies would be necessary.

4. **Provisions of the Building Code**

Article 3.3.1.7. Protection on Floor Areas With a Barrier-Free Path of Travel

(1) Except as provided in sentences (2) and (3), every floor area above or below the first storey that has a barrier-free path of travel shall

(a) be served by an elevator

(i) conforming to Sentences 3.2.6.9.(4) to (6),

(ii) protected against fire in conformance with Clauses 3.2.6.9.(3)(b) or (c), and

(iii) in a building over 3 storeys in building height, protected against smoke movement so that the hoistway will not contain more than 1% by volume of contaminated air from a fire floor during a period of 2 h after the start of a fire, assuming an outdoor temperature equal to the January design temperature on a 2.5% basis determined in conformance with Subsection 2.5.1., or

(b) be divided into at least 2 zones by fire separations conforming to Sentences (4), (5) and (6) so that

(i) persons with physical disabilities can be accommodated in each zone,

(ii) the travel distance from any point in one zone to a doorway leading to another zone shall be not more than the value for travel distance permitted by Sentence 3.4.2.5.(1) for the occupancy classification of the zone, and

(iii) a barrier-free path of travel is provided to an exit.

(2) In residential occupancies, the requirements of Sentence (1) are waived if a balcony conforming to Sentence (7) is provided for each suite, except for suites on the storey containing the barrier-free entrance described in Article 3.8.1.2.

(3) The requirements of Sentences (1) and (2) are waived when the building is sprinklered.

Sentence 3.8.2.1.(3)Areas requiring Barrier-Free Path of Travel

(3) Where a balcony is provided in a dwelling unit, access shall be provided to the balcony

(a) by a doorway with a clear width of not less than 800 mm (2 ft 7 in) when the door is in the open position, and

(b) such that no projection above the walking surface is more than 13 mm (« in).

5. **Applicant's Position**

The Applicant submitted that Sentence 3.8.2.1.(3) of the OBC is not applicable to all residential unit balconies, it is only meant for balconies which are designed with the intention of satisfying the requirements of Article 3.3.1.7.

In his view, Sentence 3.8.2.1.(3) and Article 3.3.1.7. should be considered together, not in isolation, since the two provisions are integrally linked. As the Applicant noted, Article 3.3.1.7. mandates a requirement for certain fire protection measures on floor areas with a barrier-free path of travel. This provision, however, offers several compliance options. These are; to provide a firefighters' elevator [3.3.1.7.(1)(a)], to subdivide the floor area with fire separations [3.3.1.7.(1)(b), to provide a balcony that can act as a fire refuge [3.3.1.7.(2)], or to sprinkler the building [3.3.1.7.(3)]. Sentence 3.8.2.1.(3), the Applicant argued, simply followsfrom the compliance choice found in Sentence 3.3.1.7.(2) and sets out a specific standard detailing the construction of a balcony that has been designed as a method of conforming to the general requirement for fire protection on floor areas with a barrier-free path travel. He stressed that Sentence 3.8.2.1.(3) should not be viewed as a stand alone requirement dictating the design of balconies that are not intended as barrier-free areas of refuge.

The Applicant argued that his interpretation of Sentence 3.8.2.1.(3) and Article 3.3.1.7. are based on the historical development of these particular Code provisions in both the National Building

Code (NBC) and the OBC. He presented an historical overview of the development of these provisions.

By way of background, the Applicant discussed the lack of clarity in the 1990 versions of the NBC and OBC that surrounded the issue of accessibility to balconies that were intended as areas of refuge. The problem, as the Applicant described it, was that the subject balconies were built large enough to accommodate wheelchairs, but that the curb constructed at the threshold to the balcony did not allow for wheelchair access. The 1995 NBC attempted to address this by modifying its Clause 3.3.1.7.(5)(a) to stipulate that a balcony had to provide "direct barrier-free access from the suite or floor area". While not providing precise construction standards, the Applicant noted that this provision did require that the balconies referred to in that Article had to be accessible.

When Ontario modified its Building Code in 1997, it chose not to amend Article 3.3.1.7., instead, partly due to its attempt to consolidate the barrier-free requirements, Ontario chose to modify Article 3.8.2.1. (found within Section 3.8, Barrier-Free Design) by adding a new Sentence (3). This Sentence also required access to the balcony and, in fact, went further by including precise construction requirements. The obvious intent behind this revision to the OBC, the Applicant argued, was to follow the NBC lead in developing provisions to help clarify Article 3.3.1.7. regarding balcony access, the main difference being that the OBC clarification change was made specifically to the section regarding barrier-free standards. Unfortunately, the Applicant indicated, the OBC change did not cross-reference Article 3.3.1.7. as the NBC change had done.

The Applicant also presented evidence in the form of a statement from the Chair of the 1997 Barrier-Free OBC Committee indicating that the members on that panel did not anticipate that their discussions and considerations of Sentence 3.8.2.1.(3) were intended to apply to balconies that were not designed as areas of refuge.

The Applicant also argued that it was not the intention to amend the OBC to require universal balcony accessibility because a new change of that magnitude would have gone through an extensive consultation process. This issue had no consultation, and was not discovered by Code users until after the 1997 OBC came into effect.

The Applicant asserted that many practical problems would arise if the Respondent's interpretation concerning barrier-free accessibility to all balconies was correct. Specifically, without a curb at the threshold water penetration would likely occur. In turn, this wouldcause

difficulties for condominium owners/tenants and would probably result in lawsuits and/or claims with designers, builders and the New Home Warranty Program. Design solutions to deal with water penetration are problematic and expensive, he indicated.

The 13 mm (1/2 in) allowable difference between interior and exterior grades causes other problems too. Floor finishes, for example, must be restricted to thin materials only, otherwise the 13 mm restriction will be exceeded. As well, considering usual construction tolerances, the Applicant noted that a 13 mm variation between grades is difficult to achieve. Having no sizeable threshold also causes difficulties regarding installation of baseboard heating elements. Finally, if all balconies must meet the standards for accessibility, the Applicant pointed out that smaller balconies would not be possible because they could not accommodate a wheelchair, although many such balconies have been designed and built in Ontario.

Lastly, the Applicant concluded by stating that the Respondent's position was based on a much too literal reading of the OBC. This has led to an interpretation of the Code that ignores the intent behind the said provisions. For the reasons stated above, he believes that the intent of OBC 3.3.1.7. and 3.8.2.1.(3) does not require all balconies, including those in dispute, to be barrier-free, only those that intended as areas of refuge.

6. **Respondent's Position**

The Respondent submitted that all balconies are required to be barrier-free. In his view, the Code is quite clear. Sentence 3.8.2.1.(3) explicitly states that dwelling units that have balconies must have a doorway with a clear width of at least 800 mm (2 ft, 7 in), and that no projection above the walking surface be more than 13 mm. In other words, there can be no curb or upstand at the threshold. He argued that, as an enforcement official, he must rely on the plain meaning of the provisions as set down in the OBC. As a result, he believes that Sentence 3.8.2.1.(3) requires the subject balconies to be barrier-free.

7. **Commission Ruling**

It is the decision of the Building Code Commission that the requirements of Sentence 3.8.2.1.(3) of the Building Code apply only with respect to balconies provided to satisfy Sentence 3.3.1.7.(7) of the Building Code.

8. **Reasons**

1) The introduction of the requirements in Sentence 3.8.2.1.(3) for balcony access was based on the 1995 NBC change series which clearly limits the application of balcony access to Article 3.3.1.7., "Protection on Floor Areas With a Barrier-Free Path of Travel."

2) The application of Sentence 3.8.2.1.(3) to all balconies would be contradictory to Clause 3.8.2.1.(2)(k) which exempts barrier free access within suites of residential occupancy.

3) Editorial changes to Sentence 3.8.2.1.(1) and Sentence 3.3.1.7.(7) are required for clarification purposes.

4) The Commission reviewed Appendix A to the Building Code under Sentence 3.8.2.1.(2) for direction on the intent of the code, which is consistent with the decision.

5) It is the assessment of the Building Code Commission that the intent of the Building Code in reviewing all evidence presented is that Sentence 3.8.2.1.(3) applies only to balconies used as required in Article 3.3.1.7.

RULING

1. **The Applicant**

   Mr. Stephen Martin, Project Manager, Colonnade Development Incorporated, 1 Antares Drive, Nepean, Ontario , has applied for a building permit under the *Building Code Act, 1992* to renovate the interior of an existing, two storey office building at 9 Auriga Drive Nepean, Ontario.

   1. **Description of Construction**

      The Applicant is proposing to renovate the interior of a two storey structure, classified as having a Group D - Business occupancy, with a building area of 1,420 m^2. The existing building is constructed of noncombustible construction, with non-rated fire separations. The structure is equipped with a fire alarm system, but the building is not sprinklered.

      Currently, the main entrance to the building an existing two storey lobby. A portion of the second floor, including the second storey elevator lobby and its connecting corridor , is open to the two storey lobby. This second floor area is described as a mezzanine within the two storey lobby. There are two rooms with one door each that open directly into the

second floor mezzanine. The remainder of the second floor is separated from the subject lobby by either glass or unrated partitions. An unenclosed stair at the south-east corner of the lobby, located opposite to the elevator, connects to the mezzanine area to the lobby.

Proposed for the ground floor of the lobby is a security control console to be constructed of fire-resistant materials, that would also act as a reception area.

There are two enclosed exit stairs. One stair is located at the west end of the building and it exits directly to the outside. The other exit stairs are located almost adjacent to the open stairs in the lobby. The entrance to the top of these stairs is from the open corridor, or mezzanine, on the second floor. At the bottom of the stairs, the path of egress leads through the south end of the lobby where the ground floor elevator lobby faces the bottom of the open stairs. From there egress is obtained by heading north past the security and reception areas to the centre exit doors.

The Applicant intends to use this front entrance two storey lobby, in conjunction with the enclosed centre stairs, as one of the two required exits from both floors areas.

2. **Dispute**

The issue at dispute between the Applicant and Respondent is whether the proposed installation of the subject security console in the existing two storey exit lobby, provides sufficiency of compliance with Sentence 3.4.4.4.(6) of the Ontario Building Code. Specifically, this provisions requires that exits, including the exit lobby of the subject building, be designed only for exiting. By installing a security desk in the exit lobby, the Applicant would, in effect, be using the lobby as a security area.

3. **Provisions of the Building Code**

Article 3.4.4.4.(6) Integrity of Exits

(6) An exit shall be designed for no purpose other than for exiting, except that an exit is permitted also to be designed to serve as an access to a floor area.

4. **Applicant's Position**

The Applicant submitted that the proposed design of the two storey lobby serving as exit route for the central stairs provides sufficiency of compliance with the relevant provisions

of the OBC. He noted at the outset that the disputed exit shafts and the lobby have remained as they existed prior to the proposed renovation, except for the intended addition of the security area.

The Applicant disputed that fire separations were necessary for the ground floor of the lobby as per OBC 3.4.4.2.(2)(e). He argued that the lobby area, at 69.7 m^2 (750 ft^2) and two storeys in height, is a large "smoke separated" space which, in the unlikely event that a fire were to occur, the second storey portion of the lobby could contain enough smoke that occupants of the building could exit safely. The Applicant did, however, accept the suggestion that a fire separation with a one fire-resistance rating could be constructed on the second floor of the lobby's north wall. This would effectively prevent the spread of smoke in the lobby from entering into areas on the second floor via the mezzanine and would also protect the egress route for the central stairs.

Regarding the issue of the security desk/reception area, or the integrity of the exit, the Applicant argued that since the entire building is occupied by a single tenant, the lobby area acts as the main entrance into the tenant's space. It is here, in clear view of the main entrance, where security is necessary. In his view, this is a more appropriate location, not in a room off one side of the lobby.

The desk itself, which is to be built of fire-resistant materials, he described as a control system equipped with some computer hardware. Overall, there would be very little fire load in this room. Further, as a security area it would be occupied by at least one security staff person 24 hours a day. The Applicant noted that the on-duty security staff would monitor the control panels, as well as operating as the warden responsible for initiating fire emergency and evacuation procedures.

For the above reasons, the Applicant concluded by stating that the proposed installation of a security desk in the building's exit lobby provides sufficiency of compliance with Article 3.4.4.4.(6).

5. **Respondent's Position**

The Respondent submitted that the use of the lobby as a security/reception area does not comply with certain provisions found in OBC Articles 3.4.4.2. and 3.4.4.4. They argued that as the subject lobby is an exit lobby, acting as an egress route for the central stairs, Clause 3.4.4.2.(2)(e) is applicable. This provision states that the lobby must conform to

the requirements for an exit found in Articles 3.4.4.2. and 3.4.4.4. In particular, the Respondent noted that Subclause 3.4.4.2.(2)(e)(ii) expressly requires control and supervision rooms to be separated from the lobby by a non-rated separation. Conversely, they pointed out that if such a room was located in the lobby then it must be an area exempt from a fire-resistance rating requirement, but this is not the case in the subject lobby.

As far as the installation of the security console in the lobby, the Respondent noted that Sentence 3.4.4.4.(6) does not permit anything other than exiting or access to a floor area in an exit lobby. Among the problems caused by this proposal, according to the Respondent, is the increase in fire load from the furniture and computer equipment in the lobby. Another issue is the proposed staffing of the security desk to monitor for possible occurrences of fire, i.e. the proposed "fire watch". As far as they are concerned, the staffing of the security desk to provide a "fire watch" does not exempt the building from the other relevant requirements. Even if they viewed the "fire watch" as an equivalent, the Respondent noted that they do not have the power to bind the Applicant to a continuous provision of such supervision. Because the building is equipped with a fire alarm system that provides early warning to occupants, they disputed that a "fire watch" would make the building safer in terms of fire protection.

6. **Commission Ruling**

It is the decision of the Building Code Commission that the installation of the security desk in the lobby provides sufficiency of compliance with Article 3.4.4.4.(6) of the Building Code provided the lobby is separated at the second floor by a separation having a one hour fire resistance rating along the north wall.

7. **Reasons**

i) The control desk shall be the only furniture permitted in the space.

ii) The control desk is staffed and monitored 24 hours a day.

iii) The Building Code under Article 3.4.4.2.(2)(c) permits occupancies opening onto a lobby.

iv) The lobby is permitted to be used as an exit under Article 3.4.4.2.

v) The fire separation on the second floor improves the exit design.

For the Respondent

RULING

1. **The Applicant**

   Mr. Allan Schutten, President, 1201068 Ontario Ltd., has applied for a building permit under the *Building Code Act, 1992* to construct a new steel shearing and warehouse facility at the Janco Steel Plant, 925 Arvin Avenue, Stoney Creek, Ontario.

2. **Description of Construction**

   The Applicant is proposing to construct a new, one storey steel shearing and warehouse structure with an area of 5,870.68 m^2, which includes 466.26 m^2 of office space. The building is of noncombustible construction and is equipped with a fire alarm system, but not a sprinkler system, nor a standpipe and hose system. The structure is classified as a Group F, Division 3 - Low Hazard Industrial occupancy.

The plant is to be used in the production of rolled steel, specifically plates and coils. It will also be used for the storage of the material produced in the plant, as well as similar material produced elsewhere.

3. **Dispute**

The issue at dispute between the Applicant and Respondent is whether the proposed steel shearing and warehouse facility, with an area of 5,870.68 m2 that is not equipped with a standpipe and hose system, provides sufficiency of compliance with Article 3.2.9.1. of the Ontario Building Code. Specifically, Article 3.2.9.1. requires that a building with an F3 occupancy exceeding 3,000 m^2 must be equipped with a standpipe and hose system. The steel plant proposed is 5,870.68 m^2 in building area. The Applicant has, however, proposed an alternative system of fire protection and detection.

4. **Provisions of the Building Code**

Article 3.2.9.1.

(1) Except as provided in Sentences (4) to (7), a standpipe system shall be installed in every building that

(a) is more than 3 storeys in building height

(b) is more than 14 m (45 ft 11 in) high measured between grade and the ceiling of the top storey, or

(c) is not more than 14 m (45 ft 11 in) high measured between grade and the ceiling of the to storey but has a building area exceeding the area shown in Table3.2.9.1. for the applicable building height if the building is not sprinklered.

5. **Applicant's Position**

The Applicant submitted that a standpipe and hose system may not be appropriate for the proposed building because it will be constructed entirely of noncombustible materials, such as concrete and steel. The material stored in the warehouse, steel coils and plates, is also not combustible. Only the limited material used to space the steel plates and hold the coils in place are combustible, the Applicant noted. Even the handling and shearing equipment, which is

operated by electric motors and a propane-powered tow motor, could only cause a very localized fire.

The Applicant argued, in fact, that the steel plates and coils stored in the plant would be more severely damaged by water used for fire fighting purposes than by the heat created by any localized fire. He was also concerned about accidental breakage of water pipes due to pipe rupture, etc. In fact, the Applicant stated that any uncontrolled introduction of water into the plant's manufacturing and storage areas would be catastrophic and would render the steel worthless.

In terms of providing sufficiency of compliance for the proposed omission of a standpipe and hose system, the Applicant is proposing three compensating measures. The first measure the Applicant intends to provide is a fire alarm system that includes heat detection devices, bells, pull stations and a system monitoring panel that is interconnected to the security system.

The second compensating measure that the Applicant is providing an access route around the entire plant for fire fighting purposes. He also noted that there is an adequate water supply to the site since there are two fire hydrants on the property, one located on each front corner of the lot. As well, there is a local fire hall only 4 to 5 minutes away.

The third measure proposed by the Applicant is a fire suppression system provided by a series of ABC type portable extinguishers ranging in size from a 1/2 lb. to 20 lbs., with one 15 lb. CO_2 fire extinguisher located at the plant's electrical area. The ABC fire extinguishers would be placed in the office area, the plant's overhead door, the shearing machine area, in each crane, in the tow motor, and around the perimeter of the plant at 29 m spaced intervals. He noted that even the areas that had a small potential for fire, such as the motors, are equipped with their own fire extinguishers for additional safety. The staff at the plant would also be trained to check, service and use the fire extinguishers, as well as perform other fire procedures.

The Applicant asserted that their alternative fire safety measures provide sufficiency of compliance with OBC Article 3.2.9.1. In his view, these three compensating measures, the fire alarm system, the fire fighting access routes, and the extinguishers and employee safety plan, compensate for not providing a standpipe and hose system.

6. **Respondent's Position**

The Respondent submitted that as an F3 occupancy with a building area of 5,870.68 m^2, the proposed structure is required to have a standpipe and hose system in accordance with Article 3.2.9.1. of the OBC. He indicated, however, that he does not object to the Applicant's alternative fire protection and detection system. Nevertheless, he stated that he does not have the jurisdiction to allow such a variation from the Building Code.

7. **Commission Ruling**

It is the decision of the Building Code Commission that the Janco Steel Plant building at 925 Arvin Avenue in Stoney Creek provides sufficiency of compliance with Article 3.1.9.1. of the Building Code provided that

i) A fire alarm system conforming to Section 3.2.4. of the Building Code is installed and connected to a central monitoring station.

ii) Fire department access routes are provided around the permiter of all building faces.

iii) Portable extinguishers are installed as proposed.

iv) The exemption of a standpipe and hose system is registered on title for this use only.

8. **Reasons**

i) The fire alarm system will provide early warning and central monitoring will provide notification to the Fire Department which are located within a 4-5 minute response time.

ii) The fire access routes which are not required for a building for this size will facilitate access to the whole building.

iii) A fire safety plan will be provided outlining the responsibilities of trained employees in use of fire extinguishers.

iv) Any change in use requires reconsideration of this exemption, as it is registered on title.

APPEARANCES

Mr. Neil Husband
Homeowner
Orangeville, Ontario
The Applicant

Mr. Michael A. Giles
Chief Building Official
County of Dufferin, Ontario
The Respondent

RULING

1. **The Applicant**

   Mr. Neil Husband, Homeowner, R.R. # 4, Orangeville, Ontario, is the holder of a building permit issued on August 25, 1998 under the *Building Code Act, 1992* to complete a series of interior and exterior repairs and renovations at R.R. # 1 (20 Station Street), Grand Valley (Amaranth Twp.), Ontario.

2. **Description of Construction**

   The Applicant is the owner of a three storey single-detached dwelling constructed in 1987 of combustible construction. This house has been the subject of a series of interior and exterior finished repairs and renovations, including changes to the main bathroom and master bedroom ensuite washroom. A non-water resistant type of gypsum wallboard was installed in the main bathroom and master bedroom washroom when that house was constructed in approximately 1987. These areas were then finished with a Bar ker product (a completely moisture resistant decorative wall panel).

The repairs that were undertaken in the main bathroom and master bedroom washroom were limited to recaulking of joints and repainting of the walls and the replacement of a small patch of damaged drywall. The gypsum wallboard installed in the main bath room and master bedroom washroom was not replaced with a water resistant gypsum wallboard at the time that repairs were being made to moisture damaged areas.

3. **Dispute**

The issue at dispute between the Applicant and Respondent is whether the repairs that were undertaken in the bathroom areas including keeping the non-water resistant drywall, as installed, in the main bathroom and the master bedroom ensuite washroom provides sufficiency of compliance with Subsection 9.29.2. of the Ontario Building Code at R.R. # 1 (20 Station Street), Grand Valley (Amaranth Twp), Ontario.

4. **Provisions of the Building Code**

Article 9.29.2 Waterproof Wall Finish

9.29.2.1. Where Required

(1) Waterproof finish shall be provided to a height of not less than

(a) 1 800 mm (5 ft 11 in) above the floor in shower stalls

(b) 1 200 mm (3 ft 11 in) above the rims of bathtubs equipped with showers, and

(c) 400 mm (15 3/4 in) above the rims of bathtubs not equipped with showers.

Article 9.29.2.2. Materials

(1) Waterproof finish shall consist of ceramic, plastic or metal tile, sheet vinyl, tempered hardboard, laminated thermosetting decorative sheets or linoleum.

5. **Applicant's Position**

The Applicant submitted that the Ontario Building Code requires that moisture resistant drywall be used where it provides a base for the wall finish around bathtubs and showers. In order to resolve an outstanding dispute with the municipality, the Applicant understood that repairs

would be done to the bathroom to bring it into compliance with the Building Code requirements for new construction. When repairs were done in the main bathroom and in the master bedroom washroom around the bathtubs and showers, however, an acceptable waterproof finish was not achieved because regular gypsum wallboard was maintained rather than replaced with a moisture resistant drywall, the Applicant argued.

6. **Respondent's Position**

The Respondent submitted that the building is over 5 years old, Part 11 of the Ontario Building Code would apply to the work carried out in the subject bathrooms. Notwithstanding, the Respondent stated that the only work performed in the main bathroom was recaulking of the joints and repainting of the walls, and therefore no material alterations were done in the main bathroom areas. He argued that the master bedroom washroom was repaired with a tempered hardboard product that meets the requirements of Part 11.

7. **Commission Ruling**

It is the decision of the Building Code Commission that the drywall backing installed in the main bathroom and master ensuite washroom provides sufficiency of compliance with Article 9.29.2. of the Building Code.

8. **Reasons**

i) The tempered hardboard finish does not require water resistant drywall backing as it is considered a water resistant finish under Article 9.29.2.2.

ii) Water resistant Drywall backing is required where ceramic or plastic tiles are used only under Article 9.29.10.4.

The Respondent

RULING

1. **The Applicant**

   Mr. Neil Husband, Homeowner, R.R. # 4, Orangeville, Ontario, is the holder of a building permit issued on August 25, 1998 under the *Building Code Act, 1992* to complete a series of interior and exterior repairs and renovations at R.R. # 1 (20 Station Street), Grand Valley (Amaranth Twp.), Ontario.

2. **Description of Construction**

   The Applicant is the owner of a three storey single-detached dwelling constructed in 1987 of combustible construction. This house has been the subject of a series of proposed renovations and repairs, including structural repairs (foundation, removing exterior cladding replacing wall sheathing, repairing AVB, replacing studs, installing missing tentest, reapplying exterior cladding, installing missing collar ties, etc.) and the upgrading of an existing ventilation system for the entire building. A permit was issued on July 8, 1998, to repair foundation and structural defects, including concerns about the adequacy of ventilation for this dwelling unit.

When the house was constructed, there was apparently no natural or mechanical ventilation in the unfinished basement space.

As part of the renovation, a new 110 CFM exhaust fan has been installed in the main washroom with a switch centrally located and identified as a ventilation fan. There are also two exhaust fans located in the lower powder room and master bedroom ensuite of 50 CFM each. There is also a range hood in the kitchen of 170 CFM.

Doors have been undercut to promote air movement throughout the dwelling unit when the fan system is in use.

There have also been four 102 mm (4 in) by 254 mm (10 in) grills installed between the unfinished basement and crawl space to provide air movement from the heated crawl space.

3. **Dispute**

The issue at dispute between the Applicant and Respondent is whether the natural and mechanical ventilation systems, as constructed, provide sufficiency of compliance with Subsections 9.32.2. and 9.32.3. respectively of the Ontario Building Code at R.R. # 1 (20 Station Street), Grand Valley (Amaranth Twp), Ontario.

4. **Provisions of the Building Code**

Subsection 9.32.1.General

Article 9.32.1.2Mechanical Ventilation for Dwelling Units

(1) Every *dwelling unit* that is supplied with electrical power shall be provided with a mechanical ventilation system in accordance with Subsection 9.32.3.

(See A-9.32.3. in Appendix A.)

Article 9.32.1.3Ventilation of Rooms and Spaces

(1) Except as permitted in Sentence (2), rooms or spaces in *a dwelling unit* shall be ventilated by natural means in accordance with Subsection 9.32.2.

(2) The natural ventilation of rooms or spaces required in Sentence (1) may be provided by mechanical means.

(3) Where a room or space is not provided with natural ventilation as described in Sentence (1), mechanical ventilation shall be provided to exhaust inside air from or to introduce outside air to that room or space at the rate of onehalf air change per hour if the room or space is mechanically cooled in summer, and one air change per hour if it is not.

Subsection 9.32.2. Natural Ventilation

Sentence 9.32.2.1.(1)Natural Ventilation Area

(1) The unobstructed openable ventilation area to the outdoors for rooms and spaces in residential buildings ventilated by natural means shall conform to Table 9.32.3.1.

Article 9.32.2.2.Protection From Weather and Insects

(1) Openings for natural ventilation other than windows shall be constructed to provide protection from the weather and insects.

(2) Screening shall be of rustproof material.

Subsection 9.32.3.Mechanical Ventilation

Sentence 9.32.3.2Required Mechanical Ventilation

(1) The mechanical ventilation system required in Article 9.32.1.2. shall comply with

(a) Part 6, or

(b) this Subsection for a mechanical ventilation system in a Type I, Type II or Type IV *dwelling unit*.

5. **Applicant's Position**

The Applicant submitted that the ventilation system should perform to comply with the requirements of a system serving the entire building under Article 2.1.1.7. of the Ontario Building Code. This is based on the fact that, where an existing building is subject to material alteration or repair, the 1997 OBC is applicable to the design and construction of the extensions

and those parts of the building that are subject to the material alteration or repair. This includes: requiring all rooms or spaces in a dwelling to have either natural or mechanical ventilation; unobstructed openable ventilation in unfinished basement space; protection of naturally ventilated spaces from weather and insects; requiring a heat recovery ventilator; a fresh air exchange rate of 0.3 air changes per hour; a system that resists the growth of micro-organisms.

6. **Respondent's Position**

The Respondent submitted that since this building is over 5 years old, Part 11 of the Ontario Building Code applies to the proposed work in this building. As a result, the proposed total mechanical ventilation capacity of 380 CFM meets the requirements of Part 11 of the Ontario Building Code to provide adequate mechanical ventilation.

7. **Commission Ruling**

It is the decision of the Building Code Commission that the transfer grills from the crawl space and the mechanical ventilation systems as constructed provide sufficiency of compliance with Section 9.32 of the Building Code.

8. **Reasons**

i) The Commission considers the work carried out, including repair of the kitchen exhaust system, subject to Article 11.3.1.1. of the Ontario Building Code

ii) The Building Code requirements at the time of construction permits air transfer from the crawl space to the adjacent basement as noted in Article 9.18.3.5. (1986 OBC).

iii) The additional ventilation fans provided increase the level of performance of the building.

iv) Methods were taken to mitigate moisture entry into the crawl space as part of the repair work carried out, including the installation of the electric heater.

APPEARANCES

Mr. Mike Speziale
Market Manager
IPEX Inc.
For the Applicant

RULING

1. **The Applicant**

   Mr. John Rasenberg, President, J. M. R. Mechanical and Electrical Contractors, has applied for a building permit under the *Building Code Act, 1992* for a portion of the construction of a new, six storey student residence building at Fanshawe Coll ege, London, Ontario.

2. **Description of Construction**

   The Applicant is involved in the construction of a new, Group C - residential (student residence) building. The structure is described as six stories, 13,020 m^2 (140,095.2 ft^2) in area. The building is of noncombustible construction. It is equipped with a sprinkler system, a fire alarm system and a standpipe and hose system.

   As part of the plumbing system, the Applicant is proposing to install combustible pipe throughout the subject sprinklered building, that penetrates fire separations with required fire-resistance ratings, with a modified fire stopping system. Specifically, the Applicant proposes to fill the annular space surrounding the combustible piping with a sealant.

3. **Dispute**

The issue at dispute between the Applicant and Respondent is whether the proposed installation of combustible piping through fire separations, with only the use of a sealant, in the subject building complies with Articles 3.1.9.1. and 3.1.9.4. of the Ontario Building Code. In particular, the dispute centres on the use of fire stop systems as a protective device for combustible pipe and what standards apply to the installation of the proposed fire stopping mechanism.

4. **Provisions of the 1997 Ontario Building Code**

Article 3.1.9.1. Article 3.1.9.4.Combustible Piping Penetrations

(1) Combustible sprinkler piping is permitted to penetrate a fire separation provided the fire compartments on each side of the fire separation are sprinklered.

(2) Reserved

(3) Except as permitted by Sentences (4) to (8), combustible piping shall not be used if any part of that system penetrates

(a) a fire separation required to have a fire-resistance rating, or

(b) a membrane that forms part of an assembly required to have a fire-resistance rating.

(4) Combustible piping is permitted to penetrate a fire separation required to have a fire-resistance rating or a membrane that forms part of an assembly required to have a fire-resistance rating, provided

(a) the piping is sealed at the penetration by a fire stop system that has an F rating not less than the fire-resistance rating required for the fire separation when subjected to the fire test method in CAN4-S115-M, "Standard method of Fire Tests of Firestop Systems", with a pressure differential of 50 Pa (0.007 psi) between the exposed and unexposed sides, with the higher pressure on the exposed side, and

(b) the piping is not located in a vertical shaft.

(5) Combustible drain piping is permitted to penetrate a horizontal fire separation provided it leads directly from a noncombustible water closet through a concrete floor slab.

(6) Combustible piping is permitted on one side of a vertical fire separation provided it is not located in a vertical shaft.

(7) Combustible piping is permitted to penetrate a vertical or horizontal fire separation provided the fire compartments on each side of the fire separation are sprinklered.

(8) Combustible piping not more 25 mm (1 in) in diameter containing chlorine gas is permitted to penetrate a fire separation between a chlorine gas service room built in conjunction with a public pool, and the remainder of the building.

5. **Applicant's Position**

The Applicant submitted that Sentences (5), (6), (7) and (8) of Article 3.1.9.4. provide specific exceptions that permit combustible piping to penetrate a fire separation, but these provisions do not indicate the appropriate standards for fire stopping . In particular, the Applicant noted that Sentence (7) allows combustible piping to penetrate a fire separation with the provision that the fire compartments on both sides of the separation are sprinklered. There is no mention in this Sentence of a requirement to fire stop the combustible pipe penetrations at the separation. It could be argued, he stated, that since the fire compartments were required to be sprinklered, and because sprinklers are engineered systems that are designed to control the propagation of fire either by extinguishment or containment, fire stopping systems, which also act to contain fire, may therefore not be necessary.

The Applicant further stressed this point by discussing Sentences (5), (6) and (8) that also, in his view, seem to allow exceptions to the use of fire stopping systems by way of conforming with other provisions (e.g., penetration of a horizontal separation that directly connects a noncombustible water closet through a concrete floor slab).

Nevertheless, the Applicant agreed that when using combustible piping that penetrates a fire separation, a fire stopping system was required because of other requirements in the OBC. He felt that the Code however was not clear on which standards apply to the necessary fire stopping systems. He noted that no where in Article 3.1.9.4. does it refer to the fire stopping of service penetrations requirements found in Article 3.1.9.1. of the OBC. While Sentence (1) of Article 3.1.9.1. does refer to 3.1.9.4 ., the relationship between the two provisions, seems to be only one way. The Applicant indicated that it would be useful if the Building Code Commission (BCC) provided them with some direction on this point.

The Applicant indicated that it was not their intention to ask the BCC to rule on the sufficiency of compliance of the proposed sealant and whether it would meet the fire stop test requirements found in Clause 3.1.9.1.(1)(b) or Sentence 3.1.9.4.(4), since they were not presenting that evidence to the Commission.

6. **Respondent's Position**

The Respondent party did not attend the hearing, and therefore their written submission, the Building Code Commission's Confirmation of Dispute form, was taken as their only response to this dispute.

On the Confirmation of Dispute form the Respondent submitted that the proposed installation of combustible piping, with the fire stopping system proposed, does not comply with Articles 3.1.9.1. and 3.1.9.4. of the OBC. Their position was that the penetrations of the fire separations by combustible piping should be protected with an approved fire stopping system. While they indicated that they had sympathy for the Applicant's views on the issue, they felt obliged to adhere to the conventional interpretation on the matter, specifically that combustible piping installed under Article 3.1.9.4. must also meet the fire stopping requirements of Article 3.1.9.1.

7. **Commission Ruling**

It is the decision of the Building Code Commission that combustible piping penetrating fire separations as permitted in 3.1.9.4.(7) are required to be fire stopped in accordance with 3.1.9.1. of the Building Code.

8. **Reasons**

i) The combustible piping may penetrate fire separations where compartments on each side of the fire separation are sprinklered, but fire stopping of openings is necessary.

ii) The fire stopping requirements of 3.1.9.1. apply to maintain the integrity of the fire separation.

Dated at Toronto this 3rd day in the month of December in the year **1998** for application number **1998-63.**

BCC Ruling No. 98-46-651

BUILDING CODE COMMISSION DECISION ON B.C.C. #98-46-651

IN THE MATTER OF Subsection 24 (1) of the *Building Code Act, 1992*.

AND IN THE MATTER OF Sentence 3.4.6.15.(4) of Regulation 403, as amended by O. Reg. 22/98, 102/98 and 122/98 (the "Ontario Building Code").

AND IN THE MATTER OF an application by Mr. Ronald Gagliardi, President, Venchiarutti Gagliardi Architects Inc.2651 John Street, Unit 1B, Markham, Ontario, for the resolution of a dispute with Mr. Kaz Mosielski, Chief Building Official, City of Kanata, Ontario to determine whether the proposed installation of Electroguard delayed access devices on certain exit doors provides sufficiency of compliance with Sentence 3.4.6.15.(4) of the Ontario Building Code at The Home Depot, 10 frank Highbor Place, Kanata, Ontario.

The Respondent

RULING

1. **The Applicant**

   Mr. Ronald Gagliardi, President, Venchiarutti Gagliardi Architects Inc., has received a building permit under the *Building Code Act, 1992* and is currently constructing a new, one storey retail warehouse building to be occupied by The Home Depot at 10 Frank Highbor Place, Kanata, Ontario.

2. **Description of Construction**

   The Home Depot building currently being constructed is one storey, Group E - mercantile occupancy, and is 10,497 m^2 (112,947.72 ft^2) in area. The building is of noncombustible construction. It is equipped with a sprinkler system which is supervised by the fire alarm system. The fire alarm system is monitored and provides direct notification to the local Fire Department.

   The construction of the subject building has reached the stage when finishing details, such as hardware are being installed. The Applicant is proposing to equip the exit doors around the perimeter of the warehouse with Sargent of Canada's electro nically controlled Electroguard delayed egress devices, even though these are not required by the OBC, because of their

potential for reducing theft. These mechanisms are described as an electromagnet built into the crash bar of a panic-style exit device .

3. **Dispute**

The issue at dispute between the Applicant and Respondent is whether the proposed installation of the subject delayed egress devices provides sufficiency of compliance with Sentence 3.4.6.15.(4) of the Ontario Building Code. Article 3.4.6.15. of the OBC describes the provisions for door release hardware. Specifically, Sentence (4) sets out below the conditions that must be met when installing an electromagnetic locking mechanism that does not include a latching device of some kind. With the particular delayed egress device in dispute, however, a latching mechanism is an integral part of the overall door hardware.

4. **Provisions of the 1997 Ontario Building Code**

Sentence 3.4.6.15.(4) Door Release Hardware

(4) Electromagnetic locks that do not incorporate latches, pins or other similar devices to keep the door in the closed position are permitted to be installed on an exit doors other than doors described in Sentence (5) provided

a)the building is equipped with a fire alarm system conforming to Subsection 3.2.4.,

b)the locking device, and all similar devices in the access to exit leading to the exit door, are installed as ancillary devices to the fire alarm system and release immediately upon activation of

i) the alarm signal where a single stage fire alarm system is installed,

ii) except as provided in Subclause (iii), the alert signal where a 2 stage fire alarm system is installed, or

iii) the alarm signal of a 2 stage fire alarm system installed in a care or detention occupancy

c) the locking device releases immediately upon loss of power to the fire alarm control panel or loss of power to the fire alarm control panel or loss of power controlling the electromagnetic locking mechanism and its associated auxiliary controls,

d) the locking device releases immediately upon actuation of a manually operated switch readily accessible only to authorized personnel and located near the main entrance of the building or in the central alarm and control facility of Sentence 3.2.6.12 .(1).

e) the locking device releases immediately upon a fault being detected in the electrical circuit between the fire alarm control panel and the controller of the locking device,

f) the locking device releases immediately upon the operation of a manual pull station for the fire alarm system located on the wall not more than 600 mm (23 5/8 in) from the door,

g) a legible sign having the words **EMERGENCY EXIT UNLOCKED BY FIRE ALARM** is permanently mounted on the door,

h) the lettering on the sign required in Clause (g) is at least 25 mm (1 in) high with a 5 mm (3/16 in) stroke.

i) upon release, the locking device must be reset manually by the actuation of the switch referred to in Clause (d),

j) the operation of any by-pass switch, where provided for testing of the fire alarm system causes an audible signal and a visual signal to be indicated at the fire alarm annunciator panel and at the monitoring station of Clauses 3.2.4.7.(4)(a), (b) or (c), and

k) emergency lighting is provided at the doors,

5. **Applicant's Position**

The Applicant submitted that the proposed installation of the Electroguard delayed egress devices provides sufficiency of compliance with Sentence 3.4.6.15.(4) of the OBC because it meets the release requirements found in Clauses (b) to (f) of that Sentence. As well, it also complies with Clauses (g) to (k) of Sentence (4), which set out the standards for signage, reset and safety of electromagnetic door hardware. The Applicant also indicated that the delayed egress features of the locking mechanism comply with the requirements found in the NationalBuilding Code. The Electroguard device is ULC listed both as fire exit hardware as well as controlled exit panic hardware.

The Applicant, in describing the Electroguard locking device, noted that a small magnet is located in the bar mechanism which, when armed, or energized, prevents the push pad from

being depressed for 15 seconds. This magnetic locking action is controlled electronically by circuitry contained in the bar. The activation or deactivation of the magnet does not involve the moving of any mechanical pieces such as latches or pins. The latch bolt mechanism, which provides positive locking action, is driven by the push pad itself, not the magnet. The magnet, when armed, simply prevents the bar from being depressed. Any removal of power, the Applicant noted, causes the subject door hardware to revert to a standard panic device (ULC listed), making the locking system fail-safe.

The Applicant noted as well, that the Electroguard device is also equipped with an additional release mechanism that de-energizes the electromagnetic locking assembly after 15 seconds if the panic bar is depressed for more than two seconds continuously . For these reasons, it was the Applicant's position that the electromagnetic lock was a delay device and not a latching mechanism.

By way of comparison, the Applicant claimed that the subject door hardware assembly was similar to that of other exit doors that also include both an electromagnetic lock (typically installed at the top of a door) and positive latching door hardware, but in which the devices are installed in separate locations on the door. They noted that doors with separate latching and electrolocking devices are permitted by the OBC. The Applicant further noted that the Respondent has indicated that they would allow a separate electromagnetic locking device to be installed on a door that is equipped with a latching mechanism. The fact that these two mechanisms are combined within the same panic bar is, in the Applicant's view, the only major difference between the Electroguard door hardware and more conventional doors where the hardware devices are separated.

6. **Respondent's Position**

The Respondent submitted that the proposed installation of the Electroguard electromagnetic locks does not provide sufficiency of compliance with Sentence 3.4.6.15.(4) because this device contains a latching mechanism contrary to the OBC. He argued that the net effect of the latching mechanism would be to keep the door in a closed position and thus would violate the intent behind the "immediate release" clauses in Sentence (4). While the Respondent stated that standard electromagnetic locks can sometimes be found at the top of doors that are installed with separate latching mechanisms located elsewhere on the door, he noted that Sentence 3.4.6.15.(4) specifically prohibits electromagnetic locks that incorporate a latching device. The Respondent also noted that the recently released version of the OBC did not include amendments that would

have permitted these devices. In his view, therefore, the Code still prohibits the use of such devices.

7. **Commission Ruling**

It is the decision of the Building Code Commission that the installation of the Underwriters Laboratory of Canada listed electromagnetic door securing and releasing device provides sufficiency of compliance with Sentence 3.4.6.15.(4) of the Building Code on the exit doors at the Home Depot at 10 Frank Highbor Place, Kanata.

8. **Reasons**

i) The installation will meet the requirements of Article 3.4.6.15.(b) - (k) of the Ontario Building Code.

ii) The device is listed as panic hardware and tested to insure that the electromagnetic device does not interface with the safe operation of the exiting capacity.

iii) The electromagnetic device although incorporated in the hardware operates independently of the exit door hardware. The electro magnetic device is also listed by U.L.C. for that function.

Dated at Toronto this 3rd day in the month of December in the year **1998** for application number **1998-58.**

RULING

1. **The Applicant**

   Ms. Christine Grant, homeowner, has applied for a building permit under the *Building Code Act, 1992* to renovate her existing home by adding a sunroom and a second storey and by remodelling certain existing rooms at 178 Grandview Road, Nepean, Ontario.

2. **Description of Construction**

   The Applicant is proposing to renovate an existing 1 storey, detached, Group C occupancy, dwelling unit which is located near the shore of Lake des Chenes. Her plan is to enlarge her existing house, as well as substantially renovate its interior.In terms of additions to the existing structure, it is the Applicant's intention is to construct a small sunroom located off the kitchen and diningroom and a second floor. The interior renovations consist of transforming the two existing ground floor bedrooms into a family room and storage area. Replacing these would be two new bedrooms built on the second storey. The existing ground floor laundry room would also be moved to the second floor. (A third ground floor bedroom would also be removed.) The renovations, including the addition of a second floor and sunroom, will increase the total finished area in the dwelling to approximately 200 m^2 (2,152 ft^2) from the existing 120.8 m^2 (1,300 ft^2) .

The proposed construction will increase the total fixture units from the current level of 9.5 to 18. The number of bedrooms will be reduced from three to two. The number of people living in the house will not change, it will stay at three.

The Applicant is not proposing any changes or upgrades to her existing sewage system as part of the overall work. The existing system is described as conventional Class 4 sewage treatment facility. It has a 3,600 L (800 gallon) septic tank and transmits effluent to a 91.4 m (300 ft) tile leaching bed by gravity disposal. The leaching bed has six 15 m (50 ft) runs of PVC pipe spaced 0.92 m (3 ft) apart on centre. The pipes are located approximately 60 cm (2 ft) below the surface and are reported to be resting on imported sand and gravel. The existing daily design sanitary sewage flow based on the OBC formula (assuming a 3 bedroom house with less than 20 fixture units) is 1,600 L/day. The septic tank and leaching bed are located at adequate distances from the proposed house.

The soil at the subject site is described as sand and native shale that measures between 60 to 120 cm (2 to 4 ft) in thickness above the bedrock, with the shallower soil located at the south end of the property.

The sewage system, located in the rear or south yard from the house, has a flat leaching bed area that is open and grass covered. It appears to be functioning without problems.

The water supply is piped to the subject residence from a municipal water system.

3. **Dispute**

The issue at dispute between the Applicant and Respondent is whether changes to the existing on site sewage system are required as a result of a proposed addition to the subject existing house in order to achieve sufficiency of compliance with Part 8 and Article 11.4.2.5. of the Ontario Building Code. Article 11.4.2.5., in particular Sentence (3) cited below, sets out three criteria under which the performance level of an existing building will be considered as reduced due to assumed increases in total daily design sanitary sewage flow. Situations causing a performance level reduction such as construction described in Sentence 11.4.2.5.(3), an increase in occupant load, an increase in total daily design flow, or a change in amount or type of sanitary sewage are dealt with in Sentence 11.4.3.6.(1), which states that the upgrading of the adversely affected system shall comply with Part 8 of the OBC. In the subject application, if the performance level of the building is deemed to be reduced, then upgrading of the existing sewage system in accordance with Part 8 will be required.

4. **Provisions of the 1997 Ontario Building Code**

Article 11.3.2.1. Portion of Extended Buildings

(1) Where an existing building is extended

(a) this Part applies to the existing portion of the building, and

(b) the extended portion of the building shall comply with all other Parts of the Code.

Article 11.4.2.5.Sewage Systems

(3) The performance level of an existing dwelling unit is reduced where proposed construction which,

(a) increases the number of bedrooms in the dwelling unit,

(b) exceeds 15% of the gross area of the dwelling unit, or

(c) adds new plumbing fixtures to the dwelling unit, will result in the total daily design sanitary sewage flow of the dwelling unit, calculated in accordance with Article 8.2.1.3., exceeding the capacity of any component of a sewage system serving the dwelling unit.

Article 11.4.3.5. Sewage System

(1) Where the performance level of an existing building is reduced under

Article 11.4.2.5., upgrading of a sewage system which is adversely affected by the construction, increase in occupant load, increase in the total daily design sanitary sewage flow or change in the amount or type of sanitary sewage shall be required in conformance with Part 8.

5. **Applicant's Position**

The Applicant submitted that the proposed construction will not reduce the performance level of her house regarding its sewage system. She argued that while she was increasing the total finished area of the house and the number of fixture units, the number of occupants and the total daily design flow would not increase. In the Applicant's view, since the total daily design flow was not increasing, then no component of her sewage system would exceed its capacity as is the

case in Sentence 11.4.2.5.(3). In fact, she argued that her sewage system had excess capacity. As a result, she believed that no upgrades to her existing system was necessary.

Regarding the issue of the shallow soil at the site, the Applicant argued that the existing system is functioning satisfactorily, is well maintained through regular pump outs, and shows no sign of future failure. She also indicated that they have retained an engineering firm to design a new sewage system should the current one fail. The Applicant also noted that municipal sanitary sewers are only one kilometre away, and in all likelihood would probably be extended to their area in the next few years.

6. **Respondent's Position**

The Respondent submitted that the proposed construction would add significantly more than 15 % to the area of the building. In his view, therefore, this would have a negative impact on the performance level of the building when considering Sentence 11.4.2.5.(3). This, he argued, meant that the Applicant's sewage system had to be upgraded in accordance with Part 8 of the OBC.

Further, the Respondent noted that the existing system had not been built with a permit when it was installed in 1979, nor did it meet the applicable standards at that time. In particular, he stated that he was concerned about the shallowness of the soil and the possibility that effluent has, or will eventually, travel along the bedrock and pass untreated in to Lake des Chenes.

The Respondent indicated that he offered the Applicant the option of retaining an engineer to ensure the adequacy of the existing system, or to apply for the installation of a new sewage system in conformance with Part 8 of the OBC.

7. **Commission Ruling**

It is the decision of the Building Code Commission that the performance level of the existing dwelling at 178 Grandview Road is not reduced by the proposed expansion from 120.8 m^2 to 250 m^2 and the reduction of one bedroom, and provides sufficiency of compliance with Article 11.4.2.5. of the Building Code.

8. **Reasons**

i) Evidence provided indicates, that the increased area of the dwelling unit will not increase the design sanitary sewage flow as calculated according to Table 8.2.1.3.(a) for the new floor area versus the existing building.

ii) It is the opinion of the Building Code Commission, that the performance level of the building will not be reduced, and according to Article 11.4.3.6., Part 8 does not apply.

iii) There is no increase in occupant load and no change in the type of sanitary sewage.

Dated at Toronto this 18th day in the month of November in the year **1998** for application number **1998-54.**

RULING

1. **The Applicant**

   Mr. W. K. (Bill) Evans, Manager of Maintenance, Durham District School Board, has been issued an order to comply under the *Building Code Act, 1992* to address deficiencies regarding insufficient hydrant coverage and fire department access for the 15 portable classrooms on the grounds of Lincoln Avenue Public School, at 70 Lincoln Avenue, Ajax, Ontario.

2. **Description of Construction**

   The Applicant constructed, prior to obtaining a building permit, 15 portable classrooms at Lincoln Avenue Public School. Each portable is described as being a combustible, one storey building with an area of 71.4 m^2 (768 ft^2) and is classified as having a Group A - Division 2 (Assembly - School) occupancy. All of the subject portables have two exit doors. Also, each portable is equipped with an interconnected fire alarm system that includes heat detectors and pull stations that connects to every other portable as well as to the school. As well, each portable is supplied with a fire extinguisher

The portables are situated in two groups, one containing 11 portables to the north west of the main school building, while the other group to the north east of the school contains 4 portables. In the larger grouping the portables are arranged mainly in two parallel east-west rows. The smaller group is comprised mostly of a single north-south row. The separation between each portable and from all portables to the school itself exceeds 6 m (19 ft 8 in) and 12 m (39 ft 4 in) respectively. Fire access is provided to the area of the site where the larger grouping of portable classrooms are located by an asphalt apron that surrounds most of the school, which connects to a public street by a large parking lot at the south west end of the site. Access is provided to the smaller group of portables by a level playing field to the south east of the school.

There is no fire hydrant situated within 90 m (295 ft 3 in) of the subject portables.

3. **Dispute**

The issue at dispute between the Applicant and Respondent is whether the recently constructed portable classrooms provide sufficiency of compliance with Article 3.9.3.4. of the OBC concerning the requirement to provide adequate provision for fire fighting. This provision of the 1990 OBC stipulates that where there are more than 12 portables on a school site, the fire fighting requirements regarding streets, access routes and adequate water supply are applicable. Specifically, these provisions would require that the subject group of portables be positioned so that they face a street or access route located not less than 3 m (9 ft 10 in) andnot more than 15 m (49 ft 2 in) away and that adequate water be supplied to the portables for fire fighting purposes, including providing fire hydrants within 90 m (295 ft 3 in). Currently, these provisions are not met at the 15 classroom portables at Lincoln Avenue Public School.

4. **Provisions of the 1990 Ontario Building Code**

Article 3.9.3.4. Provisions for Fire Fighting

(1) The requirements in Articles 3.2.2.6. and 3.2.5.1. to 3.2.5.8. need not be provided where there are not more than 12 portable classrooms on a site and where

(a) the distance between portable classrooms is 6 m (19 ft 8 in) or more, (see A-3.9.3., Case 1 in Appendix A)

(b) the distance between portable classrooms is less than 6 m (19 ft 8 in) and the requirements of Subsection 3.2.3. are applied between the classrooms, (see A-3.9.3., Case 2 in Appendix A)

(c) the portable classrooms are in groups where

(i) the distance between the classrooms is less than 6 m (19 ft 8 in),

(ii) the number of classrooms in a group is not more than 6,

(iii) within a group of classrooms, the facing walls have a fire-resistance rating of 45 min, rated from inside the classrooms, and

(iv) the distance between groups of classrooms is 12 m (39 ft 4 in) or more, (see A-3.9.3., Case 3 in Appendix A)

(d) the portable classrooms are in groups where

(i) the distance between the classrooms is less than 6 m (19 ft 8 in),

(ii) the number of classrooms in a group is not more than 6, and

(iii) the distance between groups of classrooms is 12 m (39 ft 4 in) or more, (see A-3.9.3., Case 4 in Appendix A) or

(e) the portable classrooms are in groups where

(i) the means of egress for each classroom within a group is by a common corridor or passageway

(ii) the number of classrooms in a group is not more than 6, and

(iii) the distance between groups of classrooms is 12 m (39 ft 4 in) or more. (See A-3.9.3., Case 5 in Appendix A).

5. **Applicant's Position**

The Applicant submitted that the construction of the subject portables was necessary due to large increases in local school enrollment. The portables, he argued, while not in fullcompliance with the OBC, are a temporary measure. In fact, he indicated that Lincoln Avenue Public School was being used by the Durham District School Board as a temporary educational facility for some staff and students that are slated to transfer to the new public school on Harkins Drive, which is scheduled to be completed by January 1999. On this basis, the Applicant insisted that the

disputed requirements of Article 3.9.3.4., such as fire routes and water supply that includes a fire hydrant, would not be necessary at the site in less than three months. Nevertheless, the Applicant argued that the existing fire route access is adequate.

The Applicant instead offered certain measures intended to demonstrate sufficiency of compliance with Article 3.9.3.4. until the completion of the Harkins Drive school in 1999:

1) All of the portables have two exit doors, whereas only one is required in the OBC.

2) The distances between all of the portables and the school itself exceeds the requirements in Article 3.9.3.4.

3) The fire alarm system, which connects all of the portables to each other and to the school, provides pull stations and heat detectors, the latter also being beyond Code requirements.

4) All portable classrooms are equipped with fire extinguishers.

5) A comprehensive Fire Safety Plan has been developed and approved by the local Fire Department. This provides for six fire drills per year.

6. **Chief Building Official's Position**

The Respondent submitted that the proposed measures do not provide sufficiency of compliance with Article 3.9.3.4. Specifically, he noted that the 15 portables do not meet the access route and fire hydrant requirements of the OBC. These deficiencies, in his view, should be corrected. While recognizing the Durham District School Board's dilemma concerning increased student enrollment due to the large degree of residential construction in Ajax, the respondent argued, however, that the safety requirements of the OBC cannot be ignored and the implementation thereof delayed. Doing so would reduce public safety and expose many parties to increased risk of liability.

7. **Commission Ruling**

It is the decision of the Building Code Commission that the portable classrooms at the Lincoln Avenue Public School provides sufficiency of compliance with Article 3.9.3.4. of the building code provided that the number of portables on site is reduced to 12 or less by February 28, 1999.

8. **Reasons**

i) The portables are equipped with 2 exits, heat detectors installed in each portable connected to the school fire alarm system on a separate zone and the system is connected to a central monitoring station.

ii) The portables are separated into 2 clusters of less than 12 portables each at least 12.2 m (40 ft) apart and 12.2 m (40 ft) from the school building.

RULING

1. **The Applicant**

   Mr. W. K. (Bill) Evans, Manager of Maintenance, Durham District School Board, has been issued an order to comply under the *Building Code Act, 1992* to address deficiencies regarding insufficient hydrant coverage and fire department access for the 16 portable classrooms on the grounds of Exeter High School, at 80 Falby Court, Ajax, Ontario.

2. **Description of Construction**

   The Applicant constructed, prior to obtaining a building permit, 16 portable classrooms at Exeter High School. Each portable is described as being a combustible, one storey building with an area of 71.4 m^2 (768 ft^2) and is classified as having a Group A - Division 2 (Assembly -School) occupancy. All of the subject portables have two exit doors. Also, each portable is equipped with an interconnected fire alarm system that includes heat detectors and pull stations that connects to every other portable as well as to the school. As well, each portable is supplied with a fire extinguisher

The portables are situated in a single group comprised of up to three irregular rows located to the east of the main school building. The separation between each portable and from all portables to the school itself exceeds 6 m (19 ft 8 in) and 12 m (39 ft 4 in) respectively. Fire access is provided to the area of the site where the portable classrooms are located by a large asphalt apron surrounding the school, which connects to a public street by a large parking lot at the south end of the site.

There is no fire hydrant situated within 90 m (295 ft 3 in) of the subject portables.

3. **Dispute**

The issue at dispute between the Applicant and Respondent is whether the recently constructed portable classrooms provide sufficiency of compliance with Article 3.9.3.4. of the OBC concerning the requirement to provide adequate provision for fire fighting. This provision of the 1990 OBC stipulates that where there are more than 12 portables on a school site, the fire fighting requirements regarding streets, access routes and adequate water supply are applicable. Specifically, these provisions would require that the subject group of portables be positioned so that they face a street or access route located not less than 3 m (9 ft 10 in) and not more than 15 m (49 ft 2 in) away and that adequate water be supplied to the portables for fire fighting purposes, including providing fire hydrants within 90 m (295 ft 3 in). Currently, these provisions are not met at the 16 classroom portables at Exeter High School.

4. **Provisions of the 1990 Ontario Building Code**

Article 3.9.3.4. Provisions for Fire Fighting

(1) The requirements in Articles 3.2.2.6. and 3.2.5.1. to 3.2.5.8. need not be provided where there are not more than 12 portable classrooms on a site and where

(a) the distance between portable classrooms is 6 m (19 ft 8 in) or more, (see A-3.9.3., Case 1 in Appendix A)

(b) the distance between portable classrooms is less than 6 m (19 ft 8 in) and the requirements of Subsection 3.2.3. are applied between the classrooms, (see A-3.9.3., Case 2 in Appendix A)

(c) the portable classrooms are in groups where

(i) the distance between the classrooms is less than 6 m (19 ft 8 in),

(ii) the number of classrooms in a group is not more than 6,

(iii) within a group of classrooms, the facing walls have a fire-resistance rating of 45 min, rated from inside the classrooms, and

(iv) the distance between groups of classrooms is 12 m (39 ft 4 in) or more, (see A-3.9.3., Case 3 in Appendix A)

(d) the portable classrooms are in groups where

(i) the distance between the classrooms is less than 6 m (19 ft 8 in),

(ii) the number of classrooms in a group is not more than 6, and

(iii) the distance between groups of classrooms is 12 m (39 ft 4 in) or more, (see A-3.9.3., Case 4 in Appendix A) or

(e) the portable classrooms are in groups where

(i) the means of egress for each classroom within a group is by a common corridor or passageway

(ii) the number of classrooms in a group is not more than 6, and

(iii) the distance between groups of classrooms is 12 m (39 ft 4 in) or more. (See A-3.9.3., Case 5 in Appendix A).

5. **Applicant's Position**

The Applicant submitted that the construction of the subject portables was necessary due to large increases in local school enrollment. The portables, he argued, while not in full compliance with the OBC, are a temporary measure. In fact, he indicated that the Durham District School Board intended to close this particular high school by June 2000 and relocate its students to two other facilities, both of which will soon be under construction. On this basis, the Applicant insisted that the disputed requirements of Article 3.9.3.4., such as fire routes and water supply that includes a fire hydrant, would not be necessary at the site in lessthan two years.

Nevertheless, the Applicant argued that the existing fire route access is adequate. Regarding the installation of a fire hydrant, he noted that at Exeter High School, the necessary water connection would require installing a pipeline over 300m in length.

The Applicant instead offered certain measures intended to demonstrate sufficiency of compliance with Article 3.9.3.4. until the completion of the other two high schools in 2000:

1) All of the portables have two exit doors, whereas only one is required in the OBC.

2) The distances between all of the portables and the school itself exceeds the requirements in Article 3.9.3.4.

3) The fire alarm system, which connects all of the portables to each other and to the school, provides pull stations and heat detectors, the latter also being beyond Code requirements.

4) All portable classrooms are equipped with fire extinguishers.

5) A comprehensive Fire Safety Plan has been developed and approved by the local Fire Department. This provides for six fire drills per year.

6. **Chief Building Official's Position**

The Respondent submitted that the proposed measures do not provide sufficiency of compliance with Article 3.9.3.4. Specifically, he noted that the 16 portables do not meet the access route and fire hydrant requirements of the OBC. These deficiencies, in his view, should be corrected. While recognizing the Durham District School Board's dilemma concerning increased student enrollment due to the large degree of residential construction in Ajax, the respondent argued, however, that the safety requirements of the OBC cannot be ignored and the implementation thereof delayed. Doing so would reduce public safety and expose many parties to increased risk of liability.

7. **Commission Ruling**

It is the decision of the Building Code Commission that the portable classrooms located at the Exeter High School provides sufficiency of compliance with Article 3.9.3.4. of the building code provided

i) An external wall hydrant on the east side of the building or fire hose cabinets, are available within the existing school building to provide fire fighting to the portable classrooms.

8. **Reasons**

i) The portables are equipped with 2 exits, heat detectors installed in each portable connected to the school fire alarm system on a separate zone and the system is connected to a central monitoring station.

ii) Water supply is being provided from within the existing school for fire fighting at the portable classroom location.

RULING

The Applicant

Mr. W. K. (Bill) Evans, Manager of Maintenance, Durham District School Board, has been issued an order to comply under the *Building Code Act, 1992* to address deficiencies regarding insufficient hydrant coverage and fire department access for the 14 portable classrooms on the grounds of Cadarackque Public School, at 15 Miles Drive, Ajax, Ontario.

1. **Description of Construction**

The Applicant constructed, prior to obtaining a building permit, 14 portable classrooms at Cadarackque Public School. Each portable is described as being a combustible, one storey building with an area of 71.4 m^2 (768 ft^2) and is classified as having a Group A - Division 2 (Assembly - School) occupancy. All of the subject portables have two exit doors. Also, each portable is equipped with an interconnected fire alarm system that includes heat detectors and

pull stations that connects to every other portable as well as to the school. As well, each portable is supplied with a fire extinguisher.

The portables are situated in a single group comprised of two parallel rows located to the east of the main school building. The separation between each portable and from all portables to the school itself exceeds 6 m (19 ft 8 in) and 12 m (39 ft 4 in) respectively. Fire access is provided to the area of the site where the portable classrooms are located by a 12.2 m (40 ft) asphalt apron at the rear, or east, of the school. In all other directions, the portables are surrounded by a level solid playground area.

There is no fire hydrant situated within 90 m (295 ft 3 in) of the subject portables.

2. **Dispute**

The issue at dispute between the Applicant and Respondent is whether the recently constructed portable classrooms provide sufficiency of compliance with Article 3.9.3.4. of the OBC concerning the requirement to provide adequate provision for fire fighting. This provision of the 1990 OBC stipulates that where there are more than 12 portables on a school site, the fire fighting requirements regarding streets, access routes and adequate water supply are applicable. Specifically, these provisions would require that the subject group of portables be positioned so that they face a street or access route located not less than 3 m (9 ft 10 in) and not more than 15 m (49 ft 2 in) away and that adequate water be supplied to the portables for fire fighting purposes, including providing fire hydrants within 90 m (295 ft 3 in). Currently, these provisions are not met at the 14 classroom portables at Cadarackque Public School.

3. **Provisions of the 1990 Ontario Building Code**

Article 3.9.3.4. Provisions for Fire Fighting

(1) The requirements in Articles 3.2.2.6. and 3.2.5.1. to 3.2.5.8. need not be provided where there are not more than 12 portable classrooms on a site and where

(a) the distance between portable classrooms is 6 m (19 ft 8 in) or more, (see A-3.9.3., Case 1 in Appendix A)

(b) the distance between portable classrooms is less than 6 m (19 ft 8 in) and the requirements of Subsection 3.2.3. are applied between the classrooms, (see A-3.9.3., Case 2 in Appendix A)

(c) the portable classrooms are in groups where

(i) the distance between the classrooms is less than 6 m (19 ft 8 in),

(ii) the number of classrooms in a group is not more than 6,

(iii) within a group of classrooms, the facing walls have a fire-resistance rating of 45 min, rated from inside the classrooms, and

(iv) the distance between groups of classrooms is 12 m (39 ft 4 in) or more, (see A-3.9.3., Case 3 in Appendix A)

(d) the portable classrooms are in groups where

(i) the distance between the classrooms is less than 6 m (19 ft 8 in),

(ii) the number of classrooms in a group is not more than 6, and

(iii) the distance between groups of classrooms is 12 m (39 ft 4 in) or more, (see A-3.9.3., Case 4 in Appendix A) or

(e) the portable classrooms are in groups where

(i) the means of egress for each classroom within a group is by a common corridor or passageway

(ii)the number of classrooms in a group is not more than 6, and

(iii)the distance between groups of classrooms is 12 m (39 ft 4 in) or more. (See A-3.9.3., Case 5 in Appendix A).

4. **Applicant's Position**

The Applicant submitted that the construction of the subject portables was necessary due to large increases in local school enrollment. The portables, he argued, while not in full compliance with the OBC, are a temporary measure. In fact, he indicated that the school superintendent responsible for this area had informed him that several of the 14 portables could be removed by September of 1999 due to a restructuring process that would witness the French Immersion Program currently being offered at Cadarackque Public School being transferred to a different

site. On this basis, the Applicant insisted that the disputedrequirements of Article 3.9.3.4., such as fire routes and water supply that includes a fire hydrant, would not be necessary at the site in less than a year. Nevertheless, the Applicant argued that the existing fire route access is adequate.

The Applicant instead offered certain measures intended to demonstrate sufficiency of compliance with Article 3.9.3.4. until the removal of a few portables in 1999:

1) All of the portables have two exit doors, whereas only one is required in the OBC.

2) The distances between all of the portables and the school itself exceeds the requirements in Article 3.9.3.4.

3) The fire alarm system, which connects all of the portables to each other and to the school, provides pull stations and heat detectors, the latter also being beyond Code requirements.

4) All portable classrooms are equipped with fire extinguishers.

5) A comprehensive Fire Safety Plan has been developed and approved by the local Fire Department. This provides for six fire drills per year.

5. **Chief Building Official's Position**

The Respondent submitted that the proposed measures do not provide sufficiency of compliance with Article 3.9.3.4. Specifically, he noted that the 14 portables do not meet the access route and fire hydrant requirements of the OBC. These deficiencies, in his view, should be corrected. While recognizing the Durham District School Board's dilemma concerning increased student enrollment due to the large degree of residential construction in Ajax, the respondent argued, however, that the safety requirements of the OBC cannot be ignored and the implementation thereof delayed. Doing so would reduce public safety and expose many parties to increased risk of liability.

6. **Commission Ruling**

It is the decision of the Building Code Commission that the portable classrooms at Cadarackque Public School provide sufficiency of compliance with Article 3.9.3.4. of the building code provided that the number of portable classrooms is reduced to 12 on the site by September 1, 1999.

7. **Reasons**

i) The portables are equipped with 2 exits, heat detection installed in each portableconnected to the school fire alarm system on a separate zone and the system is connected to a central monitoring station.

ii) The cluster of portables is within 121.9 m (400 ft) of a hydrant and accessible via asphalt pavement.

November 5, 1998

APPEARANCES

Mr. Rick Reichard, Partner
Snider Reichard March Architects
Waterloo, Ontario
Agent for the Applicant

Ms. Lynn Balfour
Deputy CBO
City of Kitchener
For the Respondent RULING

1. **The Applicant**

   Ms. Deborah Gemmel, Executive Director, Participation House Waterloo Region, has applied for a building permit under the *Building Code Act, 1992* to construct a group home known as Participation House Group Home, at 120 Tagge Street, Kitchener, Ontario.

2. **Description of Construction**

   The Applicant is currently constructing a one storey (with full basement), group home with a building area of 293.7 m^2 (3,160.2 ft^2) that is intended to house only 6 residents as well as up to 3 full time staff members. The building is of combustible construction and is classified as having a Group B, Division 3 (care) occupancy under the 1997 Ontario Building Code. The structure will not be equipped with a standpipe and hose system nor a fire alarm system, but will be supplied with an interconnected smoke detection system and a sprinkler system. This latter system will be designed and installed in accordance with the requirements of NFPA 13R, "Standard for the Installation of Sprinkler Systems in Residential Occupancies up to and Including Four Stories in Height."

3. **Dispute**

The issue at dispute between the Applicant and Respondent is whether a sprinkler system constructed to the NFPA 13R standard achieves sufficiency of compliance with Article 3.2.2.41. and Sentences 3.2.5.13.(1) and 3.2.5.13.(2) of the Ontario Building Code. Article 3.2.2.41. requires that a B3 occupancy must be sprinklered even though it may be of combustible construction. The dispute therefore centres on the type of sprinkler system that is required.

The NFPA 13R standard stipulates that a sprinkler system be designed and installed for all occupied rooms. The NFPA 13 standard, however, goes further by also requiring sprinklering in unoccupied areas such as closets and concealed spaces such as attics. Sentence 3.2.5.13.(1) states that a required sprinkler system must meet NFPA 13, whereas Sentence 3.2.5.13.(2), provides an exception to Sentence (1) by allowing low rise (four stories or less) residential occupancies to comply with the more relaxed sprinkler standards found in NFPA 13R.

If the subject group home, as a small structure intended for only a maximum of 9 people, can be considered a residential occupancy as well according to the OBC, it would be allowed to conform to NFPA 13R.

4. **Provisions of the 1997 Ontario Building Code**

Article 3.2.2.41.Group B, Division 2 or Division 3, One Storey, Sprinklered

(1) A building classified as Group B, Division 2 or Division 3 is permitted to be of combustible construction or noncombustible construction used singly or in combination, provided

(a) except as permitted by Sentence 3.2.2.7.(1), the building is sprinklered,

(b) it is not more than 1 storey in building height, and

(c)it has a building area not more than 500 m^2 (5,380 ft^2).

Sentences 3.2.5.13.(1) and (2) Automatic Sprinkler Systems

(1) Except as permitted by Sentences (2), (3) and (4), an automatic sprinkler shall be designed, constructed, installed and tested in conformance with NFPA 13, "Standard for the Installation of Sprinkler Systems". (See Appendix A.)

(2) Instead of the requirements of Sentence (1), NFPA 13R, "Standard for the Installation of Sprinkler Systems in Residential Occupancies up to and Including Four Stories in Height", is permitted to be used for the design, construction, installation and testing of an automatic sprinkler system installed in a building of residential occupancy that is not more than 4 storeys in building height.

5. **Applicant's Position**

The Applicant submitted that the group home currently under construction should be considered as residential facility under the OBC, thereby allowing the proposed NFPA 13R conforming sprinkler system to be installed. The Applicant argued that the subject group home physically resembles a house from both the exterior, with its small size, and interior, with its homelike floor plans. He noted that the construction techniques are also residential in nature. Moreover, the proposed group home will function like every other family home with the staff acting as parents and residents as children and siblings. In his view, it was not the intent of the 1997 OBC to require the more onerous NFPA 13 sprinkler standard for such small buildings of residential character and function. He suggested that smaller facilities (as measured by their floor area or occupant load) in the B3 classification be allowed to comply with NFPA 13R.

The Applicant also discussed NFPA 101, Life Safety Code, and how according to its criteria the subject group home could be considered, due to the limited number of residents and the full time staffing, as a medium to fast evacuation facility.

Considering that all occupied rooms would sprinklered (according to NFPA 13R), that fireseparations would be provided between floors and bedrooms, that interconnected smoke detectors would be installed, and that evacuation would be quick, the Applicant stated that the life safety of the residents would be adequately protected without relying upon the more rigorous NFPA 13 requirements. Besides, as he argued, the principal difference in terms of protection offered by either sprinkler systems if installed in a such a building is that a NFPA 13 system would protect both occupants and the building, whereas a NFPA 13R system would only protect the occupants. The protection of property, in the Applicant's view, is not worth the additional expense. As he noted, by employing the NFPA 13 sprinkler standard, the construction costs of these already expensive homes would increase significantly.

The Applicant also pointed out that historically there has been some confusion regarding the appropriate Building Code classification in which to determine construction standards for groups homes. He indicated that this uncertainty continued to the present 1997 version of the OBC. He

stated that many like group homes were being constructed across the province with some conforming to NFPA 13, while many others were allowed to use NFPA 13R sprinkler systems. In fact, a recent similar project in a neighbouring municipality was allowed to proceed based on a NFPA 13R proposed system.

Lastly, the Applicant indicated that many safety and accessibility features had been included in the subject home, with some of these being beyond the minimum standards required in the Code.

6. **Chief Building Official's Position**

The Respondent submitted that the subject care home is not a residential facility and thus the sprinkler system should be designed and installed according to NFPA 13. As he noted, the 1997 OBC allows a care facility to be considered as having a Group C (residential) major occupancy using the exemption found in Article 3.1.2.5. The building at hand, he argued, did not meet the criteria for this exemption however, since more than two people would require assistance to evacuate in an emergency. Therefore, in the Respondent's view, a care occupancy is not by definition a residential occupancy. A structure cannot be both a residential and a care occupancy at the same time. These occupancies are mutually exclusive in the OBC. Accordingly, a building classified as having a care occupancy does not qualify for any of the exemptions in Article 3.2.5.13. and instead must conform with NFPA 13 standards for sprinkler design and installation.

As well, the Respondent rejected the Applicant's attempt to use the definition and standards found in NFPA 101, Life Safety Code. NFPA 101 was not used in the design of the building, he noted. In his opinion, the OBC does not allow for the use of NFPA 101 as an equivalent in lieu of OBC standards.

7. **Commission Ruling**

It is the decision of the Building Code Commission that a sprinkler system constructed to NFPA 13R provides sufficiency of compliance with 3.2.5.13.(1) and (2) in the B3 occupancy constructed to 3.2.2.41. of the Building Code provided that

a) corridor and bedroom fire separations having a 3/4 hour fire rating are provided

and

b) manual initiating devices are located in supervised locations to initiate the operation of the interconnected smoke alarms.

Reasons

i)The single storey building is small in size, with limited occupant load of 6 residents and 3 supervisory staff .

ii)The additional compartmentation and early warning features provide an additional level of safety from fire.

Dated at Toronto this 5th day in the month of November in the year **1998** for application number **1998-50.**

The Applicant

Mr. Shaun Fuerth
Chief Building Official
Twp. of Sandwich South
The Respondent

RULING

1. **The Applicant**

   Mr. Don Little, Vice-President, Prestressed Systems Incorporated, applied for a building permit under the *Building Code Act, 1992* to renovate an existing facility by constructing a 418.2 m^2 (4,500 ft^2) addition to the precast concrete manufacturing plant at 4955 Walker Road, Windsor, Ontario.

2. **Description of Construction**

   The Applicant is proposing to construct a 418.2 m^2 (4,500 ft^2), one storey addition onto an existing 3126.6 m^2 (33,642 ft^2) precast concrete manufacturing plant, classified as a Group F, Division 3 (low hazard industrial) facility. The total area of the proposed renovated structure is 3544.8 m^2 (38,142 ft^2).

   The building is considered as facing one street and is constructed of non-combustible construction. The facility does not provide a fire alarm system nor a sprinkler system. The

premises are to be equipped with adequate fire extinguishers. The activity at the renovated building will continue to be the manufacture of precast/prestressed concrete products.

3. **Dispute**

The issue at dispute between the Applicant and Respondent is whether the proposed addition is required to provide a standpipe and hose system in accordance with Clause 3.2.9.1.(1)(b) of the OBC. The total area of the proposed building, at 3,544.8 m^2 (38,142 ft^2), exceeds the maximum allowable building area for an unsprinklered, one storey, building with an F3 occupancy as found in Table 3.2.9.A. The Applicant is proposing, however, certain measures to provide sufficiency of compliance with Clause 3.2.9.1.(1)(b).

4. **Provisions of the 1990 Ontario Building Code**

Clause 3.2.9.1.(1)(b)Standpipe and Hose Systems - Where Required

(1) Except as provided in Article 3.2.9.2., a standpipe and hose system shall be installed in every building that

(b) is greater in building area than the area shown in Table 3.2.9.A. for the applicable building height shown in the Table where the building

(i) is not sprinklered, and

(ii)is not more than 14 m (45 ft 11 in) high measured between grade and the ceiling of the top storey, or

5. **Applicant's Position**

The Applicant submitted that the proposed renovation is needed to make the working environment at the existing facility safer, cleaner and more productive. In his view, the standpipe and hose system is not necessary due to the fact that the proposed addition would increase the building area only slightly beyond the allowed maximum in Article 3.2.9.1. Furthermore, the Applicant argued that the addition is to be built of noncombustible construction to match the existing facility. As well, he noted that the use of the structure will remain as a manufacturing facility for precast/prestressed concrete in which fires are unlikely.

In terms of compensation to demonstrate sufficiency of compliance, the Applicant offered two specific measures:

1)The renovated structure will be equipped with adequate fire extinguishers.

2)The Fire Safety Plan in effect at the operation, which is registered with the municipal fire department, will be revised and updated to include the proposed addition.

6. **Chief Building Official's Position**

The Respondent submitted that with the proposed addition the building would exceed the allowable maximum of 3,000 m^2 (32,300 ft^2) for a one storey building containing this type of occupancy. Thus, in his view, OBC Clause 3.2.9.1. (1) (b) requires that a standpipe and hose system be installed.

7. **Commission Ruling**

It is the decision of the Building Code Commission that the addition to the building at Prestressed Systems Incorporated provides sufficiency of compliance with Clauses 3.2.9.1.(1)(b) and Table 3.2.9.A. provided that:

a) Additional portable extinguishers be provided throughout the building at twice the coverage required for this occupancy.

b)The building use and fire load remain unchanged

c)The security service is extended to include regular patrols within the building during unoccupied periods.

8. **Reasons**

i) The addition is served by two hydrant locations, one on Walker Road and one from Halford Street within approximately 121.9 m (400 ft) of the entrance to the addition.

ii) The fire department indicates that access from Halford St. via a fire hose bridge has been permitted by the property owner of lot 2020.

iii)Additional portable extinguishers are provided.

iv)The limited fuel load and lack of hazardous activities reduce the fire risk.

v)A fire safety plan acceptable to the fire department is in place.

Dated at Toronto this 5th day in the month of November in the year **1998** for application number **1998-49.**

BCC Ruling No. 98-39-644

BUILDING CODE COMMISSION DECISION ON B.C.C. #98-39-644

IN THE MATTER OF Subsection 24 (1) of the *Building Code Act, 1992*.

AND IN THE MATTER OF Sentences 3.2.2.12(1) and 3.2.4.16(5) of Regulation 61, as amended by O. Reg. 400/91, 158/93, 160/93, 383/94, 20/95 and 395/96 (the "Ontario Building Code").

AND IN THE MATTER OF an application by Mr. Jim Gillies, Vice President, Hopewell Development Corporation, 2750, 801-16th Avenue S.W., Calgary, Alberta, for the resolution of a dispute with Ms. Brenda Campbell, Chief Building Official, City of Brampton, Ontario to determine whether post-indicating valves on a looped fire main around the perimeter of an new building are required to be electrically supervised to achieve sufficiency of compliance with Sentences 3.2.2.12(1) and 3.2.4.16(5) of the 1990 Ontario Building Code at 255 Chrysler Drive, Brampton, Ontario.

RULING

1. **The Applicant**

   Mr. Jim Gillies, Vice-President, Hopewell Development Corporation, is the holder of a building permit under the *Building Code Act, 1992* to construct a 81,120m^2 (873,175 sq. ft.) distribution warehouse known as the Brampton Distribution Campus, at 255 Chrysler Drive, Brampton, Ontario.

2. **Description of Construction**

   The Applicant has recently completed construction of a one-storey, 81,120m^2 (873,175 sq. ft.) Group F, Division 2 (medium hazard industrial) warehouse. The building is non-combustible and is constructed under the "any height, any area" requirements of the 1990 OBC Article 3.2.2.55. The building is equipped with a hose and standpipe system, but is not required to have a fire alarm system.

The facility is now occupied and used by RJR Nabisco Limited as a warehouse for their products.

The building is fully sprinklered by means of an electrically-supervised sprinkler system. This system is monitored as a requirement for the unrated roof assembly. The monitoring system includes a Simplex TrueAlarm 4100 control panel which monitors all indoor fire protection valves, the pump controller for alarm and trouble, diesel fuel level, low pump room temperature, water flow in the sprinkler system, sprinkler system low pressure, and excess pressure pump power on status.

A fire main loops around the entire facility and supplies water to sprinkler systems in the project by means of eight 250mm (9.75 inch) dia. pipe connections as well as to outside hydrants. Ten divisional control post indicator valves (P.I.V.'s) and one valve in a roadway box are located in the looped fire main outside of the building in order to facilitate maintenance, alteration or repair of the hydrants and sections of the main, should the need arise. P.I.V.'s are not installed in branch es leading to individual sprinkler systems. The water in the looped fire main is pressurized by a fire pump, which is supplied from a 400mm (15.6 inch) City trunk water main.

The project was designed and constructed with an electrically supervised indicated control valve in each sprinkler system riser in the building and with high quality padlocks for the divisional control P.I.V.'s on the looped fire main around the exterior of the building.

3. **Dispute**

The issue at dispute between the Applicant and Respondent is whether the post-indicator valves located in the looped fire main must be electrically supervised.

Subsequent to a site visit by the fire department at substantial completion of construction, City building officials have indicated that they consider that the manually locked P.I.V.'s on the looped fire main do not satisfy the intent of the OBC Sentences 3.2.2.12.(1) and 3.2.4.16.(5) whereby, in respect of a sprinkler system, the movement of a control valve handle must be electrically supervised.

However, based on other indications from City officials, the applicant understands that electrical supervision of non-indicating divisional control valves in the looped fire main would not be necessary since these valves are located in road boxes.

4. **Provisions of the 1990 Ontario Building Code**

Sentence 3.2.2.12(1) Sprinklers in Lieu of Roof Rating

(1) The requirements in Articles 3.2.2.16 to 3.2.2.62. for roof assemblies to have a fire resistance rating are permitted to be waived provided

(a)the building is sprinklered

(b)the sprinkler system in Clause (a) is electrically supervised in conformance with Sentence 3.2.4.16.(5), and

(c)the operation of the sprinkler system in Clause (a) will cause a signal to be transmitted to the fire department in conformance in Sentence 3.2.4.7.(3).

Sentence 3.2.4.16(5) Sprinklers in Lieu of Heat Detectors

(5) The sprinkler system referred to in Sentence (1) shall be electrically supervised to indicate a trouble signal on the building fire alarm system annunciator for each of the following:

(a) movement of a control valve handle,

(b) loss of excess water pressure required to prevent false alarms in a wet pipe system,

(c) loss of air pressure in a dry pipe system,

(d) loss of air pressure in a pressure tank,

(e) a significant change in water level in any water storage contained used for fire fighting purposes,

(f) loss of electrical power to any automatically starting electrical fire pump, (see Appendix A) and

(g) a temperature approaching the freezing point in any dry pipe valve enclosure or water storage container used for fire fighting purposes.

5. **Applicant's Position**

The Applicant submitted that the P.I.V.'s on the Brampton Distribution Campus looped fire main are not on the branch water supply lines feeding individual sprinkler system headers, unlike some other installations where P.I.V.'s have been installed on such branches. Two of these valves would have to be shut in order to cut off water supply for all sprinkler systems.

In the applicant's opinion, review of the OBC, NFPA 13, NFPA 24 and the NFPA Automatic Sprinkler System Handbook and consideration of industry practices support the following conclusions:

1.The looped fire main, including the divisional control P.I.V.'s, is not part of the sprinkler systems; it provides water to the sprinkler system and the hydrants.

2.The divisional control P.I.V.'s located in the looped fire main are not "control valves" for a sprinkler system such as are intended to be governed by the electrical supervision requirements of OBC 3.2.4.16.(5).

3.The installation of padlocked P.I.V.'s in the looped fire main of the Brampton Distribution Campus does not represent a violation of the Ontario Building Code.

6. **Chief Building Official's Position**

The Respondent submitted that the private looped fire main supplies water to the sprinkler systems and as such, becomes an integral part of the sprinkler system. The post indicator valves control water supply to the sprinkler systems.

Sentence 3.2.4.16.(5) states that the sprinkler system shall be electrically supervised to indicate a trouble signal on the building fire alarm system annunciator for the movement of a control valve handle. Thus the post indicator valves require electrical supervision.

Notwithstanding the commitment of the current owners and their management company to maintain a rigorous maintenance programme, the commitment of future owners/mangers cannot be anticipated. The building has already changed ownership once since occupancy.

It is unreasonable to expect the Fire Department to monitor deviations from required and, therefore, anticipated performance measures.

Other than the manual locking of the valves and the commitment to a high maintenance standard, no additional measures have been introduced which can be considered to provide sufficiency of compliance. The building is not equipped with a fire alarm system.

7. **Commission Ruling**

It is the decision of the Building Code Commission that the post indicating valves on a looped fire main around the perimeter of a new building provides sufficiency of compliance with Sentences 3.2.2.12(1) & 3.2.4.16(5) of the Building Code as installed.

8. **Reasons**

i)Individual dedicated control valves to shut off the water supply to a sprinkler system are required to be electrically supervised in accordance with the Ontario Building Code and are equipped accordingly at the building entrance.

ii)The 10 exterior post indicating valves on the looped mains are installed to facilitate maintenance and shutting off one valve only does not cut off the water supply to a sprinkler system. It requires 2 valves to be closed to isolate any system. In addition, valves are secured with a high quality padlock and weekly inspections are carried out, recorded, and available to the fire department on request.

iii)The loop mains are provided from two feeds from the municipal water supply.

iv)The installation is consistent with industry practices and acceptable to the insurance carrier.

Dated at Toronto this 21st day in the month of October in the year **1998** for application number **1998-48.**

BCC Ruling No. 98-38-643

BUILDING CODE COMMISSION DECISION ON B.C.C. #98-38-643

IN THE MATTER OF Subsection 24 (1) of the *Building Code Act, 1992*.

AND IN THE MATTER OF Clauses 3.10.2.4.(2)(b) and (c) of Regulation 61, as amended by O. Reg. 400/91, 158/93, 160/93, 383/94, 20/95 and 395/96 (the "Ontario Building Code").

AND IN THE MATTER OF an application by Mr. Nabil S. Jurdak, Vice President, Secure Max Self Storage, 6300 Northcrest Ste. 10C, Montreal, Quebec, for the resolution of a dispute with Mr. Richard Hewitt, Chief Building Official, City of Ottawa, Ontario to determine whether corridor walls not constructed to be continuous from the floor to the underside of the ceiling in a self-storage facility achieve sufficiency of compliance with Clauses 3.10.2.4.(2)(b) and (c) of the Ontario Building Code at 458 Catherine Street, Ottawa, Ontario.

Mr. Chris Freeman
Chief Building Code Plan Examiner
City of Ottawa
The Respondent

RULING

1. **The Applicant**

   Mr. Nabil S. Jurdak, Vice President, Secure Max Self Storage, has applied for a building permit under the *Building Code Act, 1992* to renovate an existing 3 storey building into a self-service storage building at 458 Catherine Street, Ottawa, Ontario.

2. **Description of Construction**

   The Applicant proposes to convert an existing 3 storey, 4,684 m^2 (50418 sq.ft.) building into a self-service storage facility, classified as Group F, Division 2 - medium hazard industrial occupancy. The building contains both combustible and non-combustible construction. It is equipped with a sprinkler system and a fire alarm system, but does not have a hose and standpipe system.

   Within the storage area of the building, the applicant is proposing that the storage lockers, including the corridor walls, be constructed out of 2286mm (7 ft 6 in) high metal stud gypsum

board or galvanized steel partitions with an open mesh ceiling. The corridor walls are not built continuous from the floor to the underside of the floor above, the ceiling or the roof.

The maximum travel distance would be 15m (49 ft 3 in) from the centerline of the locker door to the nearest exit.

3. **Dispute**

The issue at dispute between the Applicant and Respondent is whether the maximum travel distance exceeds 15m (49 ft 3 in) from inside the rental space, and whether corridor walls must be constructed to be continuous from the floor to the underside of the ceiling in a self-storage facility in order to achieve sufficiency of compliance with Clauses 3.10.2.4(2)(b) and (c) of the Ontario Building Code.

4. **Provisions of the Ontario Building Code**

Clause 3.10.2.4. Safety Requirements Within Floor Areas

(2) A corridor need not be constructed as a public corridor where the travel distance, measured from inside the rental space to the nearest exit, is not more than 15 m (49 ft 3 in) provided that the corridor walls

(b)have no openings other than doors and the doors are of solid construction, and

(c)are continuous from the floor to the underside of the floor above, the ceiling or the roof.

Applicant's Position

The Applicant submitted that the 2286mm (7 ft 6 in) high metal stud gypsum board or galvanized steel partitions are adequate because the building is (or will be) sprinklered, equipped with a central fire alarm system connected to a fire station, and equipped with an intercom and 24 hour camera surveillance. A live-in caretaker will provide surveillance at all times. As well, the building has very low occupancy, with no more than 3 to 5 persons on average on a floor area. The building includes smoke detectors and a smoke exhaust system. There are no dead end corridors. The system has been in use for the last 13 years in 9 similar buildings with excellent results and efficiency.

The mesh ceiling allows surveillance of the contents of locker to identify hazardous or illegal contents.

The applicant submits that the travel distance from the locker entrance to the nearest exit is not more than 15m (49 ft 3 in).

The applicant believes the 2286mm (7 ft 6 in) corridor walls should be acceptable because of the protective measures which are outlined above, and also because of the previous BCC ruling (#94-25-403) on a similar self-service storage building application.

5. **Chief Building Official's Position**

The respondent submitted that the conditions of OBC Clauses 3.10.2.4.(2)(b) and (c) have not been met because the travel distance to the furthest portion of the rental space exceeds 15m, (49 ft 3 in) and the proposed corridor walls terminate short of the floor/ceiling construction above. According to the respondent, in a case such as this proposal where the travel distance is greater than 15m (49 ft 3 in), as measured from inside the rental space to the nearest exit, the Code requires the corridor walls to be constructed as a public corridor in accordance with 3.3.1.4.

6. **Commission Ruling**

It is the decision of the Building Code Commission that the 7.5 foot (2286 mm) high non combustible partitions walls in the self storage and facility provides sufficiency of compliance with Clauses 3.10.2.4(2)(b) & (c) of the building code.

7. **Reasons**

i)The travel distance to an exit from any locker entrance is 15 m (49 ft 3 in) or less.

ii)The building is provided with smoke and heat detection; the building will be sprinklered throughout and is provided with a connection to a central monitoring station.

iii)The control over the building occupancy rests with the building management and not with and the individual lessees.

iv)The partition walls required to be continuous to the underside of the floor slab are not required to have a fire resistance rating.

v)The compartment sizes are limited which will limit the degree of fire involvement.

vi)Smoke exhaust is provided on each floor.

vii)A surveillance system is provided that will control and monitor the amount and type of combustibles in the lockers.

It is the opinion of the building code Commission that with the limited occupant load, the sprinkler protection provided, the limited distance of travel, the control of the building by the owner, the installation of smoke exhaust and the connection of the fire alarm system to a central monitoring station, does not provide a hazard to Life Safety for the occupants.

Mr. Mina Tesseris
The Respondent

RULING

1. **The Applicant**

   Mr. David Beard of St. George's Anglican Church has received a correction notice to alter the recently constructed ramp to comply with the requirements of Article 3.7.3.4. of the Ontario Building Code at St George's Anglican Church,Marsh Street, Clarksburg, Ontario.

2. **Description of Construction**

   In 1997, St. George's Anglican Church was expanded through the construction of a 22.6 m^2 addition to the south west portion of the church to facilitate wheel chair access to the church and to provide an accessible washroom. The original specification was to construct a ramp in accordance with Ontario Building Code (OBC) Article 3.7.3.4. However, the lower ramp was constructed at a slope greater than the maximum permitted in the OBC, estimated at 1 in 9.2.

3. **Dispute**

   The issue at dispute between the Applicant and Respondent is whether access to St. George's Anglican Church achieves sufficiency of compliance with the requirements of Article 3.7.3.4. of the Ontario Building Code. This Article requires that the maximum slope for a ramp is 1 in 12,

although the ramp was constructed with the lower portion having a slope of approximately 1 in 9.2.

4. **Provisions of the Ontario Building Code**

Article 3.7.3.4. Ramps

(1) Ramps located in a barrier-free path of travel shall

(a)have a minimum width of 870 mm (2 ft 10 in) between handrails,

(b)have a maximum gradient of 1 in 12, (see Appendix A)

(c)have a level area of at least 1.5 m (4 ft 11 in) by 1.5 m (4 ft 11 in) at the tops and bottom of a ramp and where a door is located in a ramp, so that the level area extends at least 600 mm (23 5/8 in) beyond the latch side of the door opening, except that where the door opens away from the ramp, the area extending beyond the latch side of the door opening may be reduced to 300 mm (11 3/4 in),(see Appendix A).

(d)have a level area at least 1.5 m (4 ft 11 in) long and at least the same width as the ramp

(i)at intervals of not more than 9 m (29 ft 6 in) along its length, and

(ii)where there is an abrupt change in the direction of the ramp,

(e)except as provided in Sentence (2), be equipped with handrails and guards on both sides conforming to Articles 3.4.6.4. and 3.4.6.5, and

(f)be provided with a curb at least 50 mm (2 in) high on any side of the ramp where no solid enclosure or guard is provided.

(2) Where a ramp serves as an aisle way for fixed seating, the requirements for handrails in Clause 3.7.3.4.(1)(e) need not apply.

(3) Floors or walks in a barrier-free path of travel having a slope steeper than 1 in 20 shall be designed as ramps. (See Appendix A.).

5. **Applicant's Position**

The Applicant submitted that this ramp has a double railing on both sides. It is heated by underground piping. Everyone connected with the Church is very pleased with the new ramp which permits an easy and safe entrance for the disabled. During the ramp construction, it was discovered by the contractor that the drawings submitted did not take into consideration the fact that the lower portion of the ramp had to meet the sidewalk to the existing main entrance to the Church sanctuary. With a slope of 1 in 12 as specified in the Code, this would require both sidewalks to be on different levels where they meet. It would make both entrances awkward and dangerous.The contractor was unable to reach Mr. Bumstead on short notice to obtain his approval. The contractor accordingly completed the construction so that both the ramp and the sidewalk entrance way to the Church met on the same level. This increased the gradient, but was necessary due to space restrictions. The accessible entrance and the main church entrance are used only for worship on Sundays and for weddings funerals as required.

6. **Chief Building Official's Position**

The Respondent submitted that the ramp slope of 1 in 9.2 exceeds the allowable maximum slope of 1 in 12 for a barrier free path of travel. The building is an A2 occupancy used as a church and therefore is not subject to the exceptions stated in OBC 3.7.1.1.(1). The Chief Building Official does not have the authority to accept a ramp slope greater than prescribed in the OBC.

7. **Commission Ruling**

It is the decision of the Building Code Commission that the exterior ramp constructed to provide barrier free access of travel provides sufficiency of compliance with

Article 3.7.3.4 of the 1990 Ontario Building Code.

8. **Reasons**

i)The ramp is provided with hand rails on both sides.

ii)Heating is provided on the ramp to keep it free of ice and snow accumulation.

iii)The ramp has been in use since November 1997 by the disabled with no difficulties noted by church members.

iv)The ramp is used normally during church services when greeters are available to provide assistance if necessary.

v)Site limitations have made it difficult to comply in total with the Building Code.

vi)It is the opinion of the Building Code Commission that the ramp does not provide an unsafe condition.

Mr. Mani Navabi
The Respondent

RULING

1. **The Applicant**

   Ms. Mary-Jane Tushingham, Previous Owner, has applied for a building permit under the *Building Code Act, 1992* for a six storey residential condominium currently under construction at 7365 Martin Grove Road, Woodbridge, Ontario.

2. **Description of Construction**

   The Applicant has applied to construct a six storey, 11,810 m^2 (127,141 sq. ft.) residential condominium for seniors. The building is proposed to be of non-combustible construction with a fire alarm system and standpipe and hose system.

   The applicant is proposing to create a dead end corridor of approximately 7.2 m (23.0 ft. 8 in.) on floors 2 to 6 by extending the corridor approximately 1.0m past the last suite entry, and by placing a door to an exterior balcony at the end of the dead end corridor.

3. **Dispute**

   The issue at dispute between the Applicant and Respondent is whether the proposed design of a residential building achieves sufficiency of compliance with Sentence 3.3.1.9.(9) as it relates to the maximum length of a dead end corridor of the 1990 Ontario Building Code.

4. **Provisions of the 1990 Ontario Building Code**

Sentence 3.3.1.9.(9) Corridors

(9) In a residential occupancy, except for corridors served by a single exit as described in Sentence 3.3.4.4.(7), a dead end public corridor is permitted provided it is not more than 6 m (19 ft 8 in) long.

5. **Applicant's Position**

The Applicant submitted they wish to receive a concession from 3.3.1.9.(9) as the corridor will extend approximately 1.2m (4 ft.) past the last suite entry on floors 2 to 6 on the proposed residential building. This situation places a door to an exterior balcony further than the distance allowable for a corridor having access in a single direction for exiting purposes. This situation and placement of the balcony door is not acceptable to the City of Vaughan.

In correspondence to the City of Vaughan, the applicant states that this situation has arisen because of certain restrictions that have been encountered on site due to plumbing rough-ins happening in advance of drywalling.

At the hearing the applicant proposed additional compensating measures including:

a)a smoke detector in each suite in the dead end,

b)a fire alarm audible device on the common balcony,

c)a zero hour rated fire door with self-closer and latch, between the balcony and the corridor, and

d)the prohibition of furniture and carpeting within the balcony provided within the condominium agreement.

6. **Chief Building Official's Position**

The Respondent submitted that the a portion of the public corridor on the 2nd through 6th floors of this residential senior citizens' building has a dead end length of 7.2 m (23.0 ft. 8 in.).

The Applicant has requested that a 7.0m long dead end corridor be accepted in this building on the above noted floors in contravention with Sentence 3.3.1.9.(9).

7. **Commission Ruling**

It is the decision of the Building Code Commission that the dead end corridor in excess of 6.0m and additional compensating measures presented at the hearing do not provide sufficiency of compliance to the requirements of the Building Code.

8. **Reasons**

1.The proposed dead end corridor measuring 7.2m long exceeds the requirement of 6.0m of Article 3.3.1.9.

2.The additional compensating measures including:

a) a smoke detector in each suite in the dead end,

b) a fire alarm audible device on the common balcony,

c) a zero hour rated fire door with self-closer and latch, between the balcony and the corridor, and

d) the prohibition of furniture and carpeting within the balcony provided within the condominium agreement, in the opinion of the Building Code Commission do not provide sufficiency of compliance.

DATE OF RULING

August 26, 1998

APPEARANCES

Mr. Peter Gass
The Applicant

Mr. Brian Horsman
The Respondent

RULING

1. **The Applicant**

   Mr. Peter Gass, President, BPF Holdings Ltd., property owner, has received a final inspection report to alter the exit doors to conform to the original application for a building permit under the *Building Code Act, 1992* to construct a new two storey micro dairy facility at Miss Jersey's Dairy, c/o BPF Holdings, 1193 Fisher Street, North Bay, Ontario.

2. **Description of Construction**

   The Applicant has recently completed construction of a two storey plus basement micro dairy facility with a building area of 4,800 sq. ft. of F3 major occupancy and subsidiary retail outlet. The building is of primarily non-combustible construction. A fire alarm system or standpipe and house system were not required.

   The permit drawings approved by the City of North Bay indicated that the exit doors numbers 112, 115, 117 and 119 were to be 900 mm (3 ft.).

   During the final inspection it was discovered that two exit doors from the basement and two exit doors from the second story were installed that are less than 2 ft. 7 in (790mm) in width (three

doors 2 ft. 5 « in. and one door 2 ft. 6 in. in width) contrary to the minimum requirements of the Building Code.

The basement has an occupant load of 5 persons and contains storage and a mechanical room. The second floor level also has an occupant load of 5 persons and contains storage, a milk testing laboratory, washrooms and a staff room.

3. **Dispute**

The issue at dispute between the Applicant and Respondent is whether the four subject exit doors at widths ranging from 746 mm (2 ft, 5 « in) to 760 mm (2 ft, 6 in) provides sufficiency of compliance with Clause 3.4.3.1.(2)(e) of the 1990 Ontario Building Code.

4. **Provisions of the 1990 Ontario Building Code**

Clause 3.4.3.1.(.2)(e) Exit Width

(2) The required width of an exit shall be not less than

(e)790 mm (2 ft. 7 in.) for doorways not serving patients.

5. **Applicant's Position**

The Applicant submitted that the exit doors meet sufficiency of compliance with the requirements of the 1990 Ontario Building Code because of the minimal occupant load of the floor areas served.

The basement has an occupant load of 5 persons and contains storage and a mechanical room. The second floor level also has an occupant load of 5 persons and contains storage, a milk testing laboratory, washrooms and a staff room.

The exit doors in dispute were originally specified to be 3 ft. (900mm) in width but were not constructed as shown in the plans.

6. **Chief Building Official's Position**

The Respondent submitted that the architect's door schedule shown on drawing number A11 indicates that exit door numbers 112, 115, 117 and 119 shown on drawing number A3 are to be 3 ft. (900mm.) in width which complies with the 1990 Ontario Building Code.

The Chief Building Official was notified by the architect that the exit doors were not constructed in accordance with the plans and asked if the doors could be accepted as installed.

The Chief Building Official told the applicant that the doors could not be accepted as installed because they to not conform to the requirements of the 1990 Ontario Building Code.

7. **Commission Ruling**

It is the decision of the Building Code Commission that exit doors from the building as constructed provide sufficiency of compliance with Clause 3.4.3.1.(2)(e) of the Building Code provided that a fire alarm system conforming to Section 3.2.4. is installed throughout the building.

8. **Reasons**

I)An early warning system is provided to alert occupants of a fire condition.

ii)The occupant load of the basement and 2nd floor is low (approx. 5 persons/floor).

iii)The building is primarily of non-combustible construction.

iv)It is the opinion of the Building Code Commission that the current building use provides an adequate level of safety.

For the Respondent

RULING

1. **The Applicant**

   Mr. John Lambe, President, Better Beef Ltd., is the holder of a building permit under the *Building Code Act, 1992* to construct a new, two storey, freezer warehouse facility known as the Better Beef Freezer Warehouse at 180 Watson Road, Guelph, Ontario.

2. **Description of Construction**

   The Applicant recently constructed a two storey, 12,278 m^2 (132,111 ft^2) freezer warehouse facility, classified as a Group F, Division 3 - low hazard industrial occupancy. The building is equipped with an electronically supervised sprinkler system, but not a standpipe and hose system nor a fire alarm system. It is constructed of noncombustible construction and is considered to face one street. The building permit was issued under the 1990 version of the Ontario Building Code.

   In order to provide better insulating properties in the subject freezer facility, as part of the construction the Applicant installed 12.2 m (40 ft.) high factory assembled EPS Thermoplastic Panels on an exterior wall and certain interior walls. The subject walls, manufactured by Isowall

Ltd., are composed of expanded polystyrene insulation with a 0.38 mm (0.015 in.) thick sheet steel skin adhered to both sides. The EPS wall assembly does not rely on the rigidity of the insulation for structural support, this is provided independently. Some of the EPS walls installed in the freezer warehouse are 190 mm (7 1/2 in.) thick, while others are 254 mm (10 in.). One interior wall assembly combines 102 mm (4 in.) of 1 hour rated Isoroc with 153 mm (6 in.) of EPS Thermoplastic Panelling.

The insulation component of the EPS panels is combustible. It melts at 205°C (400°F) and when in liquid form has a flash point of approximately 425°C (800°F). The insulation has a flame-spread rating of 115. The panels are to be protected on all interior sides by overhead sprinklers mounted in the ceiling that will activate automatically at 141°C (286°F).

3. **Dispute**

The issue at dispute between the Applicant and Respondent is whether the installed combustible EPS Thermoplastic Panels on several interior walls and one exterior wall of the Better Beef Freezer Warehouse are permitted in a building required to be of noncombustible construction that is equipped with a sprinkler system. Sentence 3.1.5.11.(6) of the Ontario Building Code permits thermoset foamed plastic insulation on exterior walls of a building required to be of noncombustible construction under certain conditions. The Applicant has installed, however, the thermoplastic, not the thermoset, type of insulation. As well, theyhave used these wall panels on mainly interior walls.

OBC Sentences 3.1.5.11.(3) and (4) permit combustible insulation, including thermoset and thermoplastic, in noncombustible buildings for exterior and interior walls respectively both with the condition that the insulation be protected by either a standard thermal barrier, or that the thermal barrier be tested in conformance with CAN4-S101-M, "Standard Method of Fire Endurance Tests of Building Construction and Materials." If the subject EPS Thermoplastic Panel exterior and interior installations are found to be ineligible regarding the conditions for thermoset plastic insulation found in Sentence 3.1.5.11.(6), the Applicant may be required to provide a thermal barrier as per Sentences 3.1.5.11.(3) and (4). Such thermal barriers, as part of a complete wall assembly, may also need to be appropriately tested.

4. **Provisions of the Ontario Building Code**

Article 3.1.5.11.Combustible Insulation and its Protection

(3) Combustible insulation having a **flame-spread rating** of more than 25 but not more than 500 on any exposed surface or any surface that would be exposed by cutting through the material in any direction, is permitted in the exterior walls of a **building** required to be of **noncombustible construction** provided the insulation is protected from adjacent space in the **building,** other than adjacent concealed spaces within the **attic or roof spaces**, crawl spaces, and wall assemblies, by a thermal barrier as described in Sentence (2), except that in unsprinklered *buildings* more than 18 m (59 ft 1 in) high or in unsprinklered **buildings** regulated by the provisions of Subsection 3.2.6., the insulation is protected by a thermal barrier consisting of

(a)gypsum board not less than 12.7 mm (1/2 in) thick, mechanically fastened to a supporting assembly independent of the insulation and with all joints either braced or taped and filled,

(b)lath and plaster, mechanically fastened to a supporting assembly independent of the insulation,

(c)masonry or concrete not less than 25 mm (1 in) thick, or

(d)any thermal barrier that, when tested in conformance with CAN4-S101-M, "Standard Methods of Fire Endurance Tests of Building Construction and Materials", will not develop an average temperature rise of more than 140øC (252øF) or a maximum temperature rise at any point of more than 180øC (324øF) on its unexposed face within 10 min.

(See also Sentence 3.2.3.7.(3).)

(4) Combustible insulation having a **flame-spread** rating of more than 25 but not more than 500 on any exposed surface or any surface that would be exposed by cutting through the material in any direction, is permitted in the interior walls of a **building** required to be of **noncombustible construction** provided the insulation is protected fromadjacent space in the **building**, other than adjacent concealed spaces within **attic or roof spaces**, crawl spaces, and wall assemblies, by a thermal barrier as described in Sentence (2), except that in unsprinklered **buildings** more than 18 m (59 ft 1 in) high or in unsprinklered **buildings** regulated by the provisions of Subsection 3.2.6., the insulation is protected by a thermal barrier consisting of

(a)Type X gypsum board not less than 15.9 mm (5/8 in) thick conforming to CSA A82.27-M, "Gypsum Board Products", mechanically fastened to a supporting assembly independent of the insulation and with all joints either backed or taped and filled,

(b)non-**loadbearing** masonry or concrete not less than 50 mm (2 in) thick,

(c)**loadbearing** masonry or concrete not less than 75 mm (3 in) thick, or

(d)any thermal barrier that, when tested in conformance with CAN4-S101-M, "Standard Methods of Fire Endurance Tests of Building Construction and Materials", will not develop an average temperature rise of more than 140øC (252øF) or a maximum temperature rise at any point of more than 180øC (324øF) on its unexposed face within 20 min and will remain in place for not less than 40 min.

(6) Thermosetting foamed plastic insulation having a **flame-spread rating** of not more than 500 which forms part of a factory-assembled exterior wall panel that does not incorporate an air space is permitted to be used in a **building** required to be of **noncombustible construction** provided

(a)the foamed plastic is protected on both sides by sheet steel not less than 0.38 mm (0.015 in) thick which will remain in place for not less than 10 min when the wall panel is tested in conformance with CAN4-S101-M, "Standard Methods of Fire Endurance Tests of Building Construction and Materials",

(b)the**flame-spread rating** of the wall panel, determined by subjecting a sample including an assembled joint to the appropriate test described in Subsection 3.1.12., is not more than the **flame-spread rating** permitted for the room or space which it bounds,

(c)the **building** does not contain a Group B or Group C **major occupancy**, and

(d)the **building** is not more than 18 m (59 ft 1 in) high, measured between **grade** and the floor level of the uppermost **storey**.

5. **Applicant's Position**

The Applicant submitted that while EPS thermoplastic is designed differently, it is no more hazardous than thermoset plastic in terms of fire conditions in a fully sprinklered building. As a result, they argued that Sentence 3.1.5.11.(6) and the conditions contained therein were applicable.

In terms of meeting the requirements, or at least the intent, of this provision of the OBC it was their opinion that the automatic sprinkler system would provide adequate fire and life safety

protection for the building and its occupants. The Applicant indicated that the 141^{o} C (286^{o}F) sprinkler heads will activate early enough in the development of a fire that they will prevent the insulation from melting, or will serve to re-solidify it if melting has begun. Testing of the subject wall assembly was, in their view, therefore not necessary.

6. **Chief Building Official's Position**

The Respondent submitted that the EPS Thermoplastic Panels should not be considered under Sentence 3.1.5.11.(6) of the OBC since, as they noted, the insulation in question is not thermoset but thermoplastic. As a result, the Respondent argued that both Sentences 3.1.5.11.(3) and (4) were applicable. These provisions set out requirements for combustible insulation (within a certain flame-spread range), including EPS thermoplastic, for both interior and exterior wall assemblies.

In terms of meeting the specific conditions of Sentences (3) and (4), the Respondent indicated that the 0.38 mm (0.015 in.) sheet steel skin most likely did not meet the thermal barrier requirements. Further, if such a wall assembly could be considered as having a thermal barrier, it would need to undergo relevant testing to prove that the sheet steel was adequate as a thermal barrier. They noted that the installed wall panels had not been properly tested. If the panels were found to have inadequate thermal barriers, the Respondent stated that these would have to be added. Moreover, even assuming the subject wall panels could be subject to the requirements of Sentence 3.1.5.11.(6), they would still need to be tested.

Lastly, the Respondent countered the Applicant's arguments concerning meeting the intent of the OBC by sprinklering the building by pointing out that according to Article 3.2.2.61., under which the building was constructed, sprinklers are required in any case.

7. **Commission Ruling**

It is the decision of the Building Code Commission that the E.P.S. Thermoplastic interior and exterior wall panels do not provide sufficiency of compliance with 3.1.5.11.(6) of the Ontario Building Code.

8. **Reasons**

i)The provisions of 3.1.5.11.(6) are for thermosetting plastic insulation sandwich panels and not thermoplastic insulation.

ii)The 1997 Building Code has a provision for the use of foam plastic panels under 3.1.5.11.(7). No evidence was provided to the Commission that tests prescribed in 3.1.5.11.(7) have been met.

Mr. Daniel Piescic, Assistant Building Commissioner
City of Windsor, Ontario
For the Respondent

RULING

1. **The Applicant**

   Dr. William Miletic, President, Wm. Miletic Enterprises Inc., Windsor has received a correction order under the *Building Code Act, 1992* to alter the recently constructed offices to provide at least one 1,060 mm (3 ft., 6 in.) wide barrier-free path of travel at Wm. Miletic Enterprises Inc., 1730 Huron Church Road, Windsor, Ontario.

2. **Description of Construction**

   In 1994 and 1995 the Applicant renovated the space leased in the subject building to create an office for his dental practice. During construction, it was discovered that the office did not provide a barrier-free path of travel measuring 1,060 mm (3 ft., 6 in.). A correction order was issued on February 5th, 1995.

   The subject office is a one storey, 221.7 m^2 (2,386 ft^2), Group D - Business and Personal Service occupancy. The office design has two parallel corridors leading from the front to the rear, where the barrier-free washroom and two of the rooms with dental chairs are located. Both corridors are measured at 1,010 mm (3 ft., 4 in.) in width.

Since the office space is leased, the renovations completed by the Applicant were interior only. The building is constructed of noncombustible construction.

3. **Dispute**

The issue at dispute between the Applicant and Respondent is whether the as constructed hallways in the subject dental office provides sufficiency of compliance with Sentence 3.7.1.3.(1) of the Ontario Building Code. This provision requires that barrier-free paths of travel for wheelchairs must be at least 1,060 mm (3 ft., 6 in.). The hallways in the Applicant's office are currently measured at 1,010 mm (3 ft., 4 in.).

4. **Provisions of the Ontario Building Code**

Article 3.7.1.3.Barrier-Free Path of Travel

(1) Except as required in Sentence (4) and except as permitted in Subsection 3.7.3., every barrier-free path of travel shall provide an unobstructed width of at least 1,060 mm (3 ft., 6 in.) for the passage of wheelchairs.

5. **Applicant's Position**

The Applicant submitted that while the path of travel does not meet the required width found in the OBC, he argued that only a small portion of the subject hallway is not in compliance. Further, the Applicant argued that moving the walls in the deficient hallways would be difficult due to the design of the patient rooms and the placement of equipment in those rooms. Such construction would be costly and may cause a loss of business.

The Applicant also noted that the deficiency has not caused problems for any of his patients. To support this assertion, he provided a signed statement from his patients who use wheelchairs indicating that the "office was satisfactory in meeting all their special needs." As the Applicant noted, the office's design presents no fire or safety risk since wheelchairs and even stretchers are able to pass through both hallways without obstruction.

As well, because there are two hallways this offers all patients an additional route of egress.

Three proposals were offered by the Applicant as compensating measures to demonstrate sufficiency of compliance. Specifically, he proposed that signs be posted at either end of the deficient corridors indicating the undersized dimensions. He also offered to upgrade the lighting

in the hallways if necessary. As well, an intercom system could be installed to assist staff and wheelchair patients to communicate about moving through the office.

Finally, the Applicant indicated that the deficiency resulted from a change of contractors during construction. It was not his intention to willfully compromise the standards in the Building Code.

6. **Chief Building Official's Position**

The Respondent submitted that the as constructed office does not meet the requirements found in Article 3.7.1.3. of the OBC regarding minimum path of travel widths for wheelchairs. They noted that the hallways are 50 mm (2 in.) too narrow. Windsor, the Respondent indicated, has a pro-active stance on issues concerning barrier-free accessibility.

7. **Commission Ruling**

It is the decision of the Building Code Commission that the existing corridor of 1,010 mm (3 ft., 4 in.) in width does not provide sufficiency of compliance with 3.7.1.3. of the Building Code.

8. **Reasons**

i)The new south wall of the sterilization room in the corridor can be revised to provide the minimum width of 1,060 mm (3 ft., 6 in.).

ii)The width of 1,060 mm (3 ft., 6 in.) is considered minimum to allow independent mobility of handicapped patients.

RULING

1. **The Applicants**

   Mr. Dennis Farkas and Ms. Barbara Farkas, business and property owners, Sheree Fashions, have applied for a building permit under the *Building Code Act, 1992* to construct an intermediate floor area in the recently constructed addition at Sheree Fashions, R. R. # 2, Port Colbourne, Ontario.

2. **Description of Construction**

   The Applicant recently constructed a one storey, 184 m^2 (1,984 ft^2) addition onto a single storey, 91 m^2 (977 ft^2) existing building. Both the existing building and the addition are constructed of combustible construction. The structure is classified as a Group E - mercantile major occupancy. The building is not provided with a standpipe and hose system, a fire alarm system, nor a sprinkler system. The renovated building is to be used as a storage area, office and garage for the Applicant's garment business. The building permit for the addition was issued under the 1990 version of the Ontario Building Code.

   Due to complications that arose during construction of the addition, the Applicant proposed to construct an intermediate floor area between the ground floor and ceiling in the addition. The proposed mezzanine had an area of 132 m^2 (1,426 ft^2), which represented approximately 72 % of

the area of the addition. This included a balcony that extended from the main mezzanine area found over the garage and office spaces completely around the interior of the new addition. Stairs serving the mezzanine would have been accessible only by travelling over the balcony areas. Believing they had approval for this revision, the Applicants proceeded to construct such a mezzanine. An order to comply from the municipality soon followed.

Attempting to rectify this situation, the Applicants redesigned the subject mezzanine so that it covered only the smaller garage and office areas. The area of the proposed modified mezzanine is 69 m^2 (744 ft^2), which comprises roughly 37.5 % of the area of the new addition. The new design has relocated the stairs so that they directly serve the smaller mezzanine. The Applicants also proposed to maintain the existing washroom located at the opposite end of the addition from the office and garage areas. The washroom has an area of 8.5 m^2 (91 ft^2), or 4.6 % of the addition's floor area and had been built as per the plans originally submitted. The spans installed above both the washroom and the garage and office areas (50 x 254 mm (2 x 10 in) s.p.f. beams at 407 mm (16 in) on centre and Nascor I-beams NJ10 joists at 204 mm (8 in) on centre respectively) are capable of supporting substantial live and dead loads.

3. **Dispute**

The issue at dispute between the Applicant and Respondent is whether the modified intermediate floor proposal can be considered as a mezzanine in accordance with Sentences 3.2.1.1.(3) and 3.2.8.2.(1) of the Ontario Building Code. Sentence 3.2.1.1.(3) requires, in particular, that the aggregate of the intermediate floor area be no more than 40 % of the room or storey in which it is located. The total of all intermediate floor space in the addition, at 42.1 %, slightly exceeds the 40% requirement.

4. **Provisions of the Ontario Building Code**

Sentence 3.2.1.1.(3)Exception to Building Height in Storeys

(3) Except as provided in Sentences (4), (5) and (8), a mezzanine should not be considered as a storey in calculating building height provided

(a) the aggregate area of the mezzanine floor is not more than 40 per cent of the area of the room or storey in which it is located,

(b) it is used as an open floor area except as provided in Sentence 3.3.2.11.(2), and

(c) the space above the mezzanine floor has no visual obstructions more than 1,070 mm (3 ft, 6 in) above such floors.

5. **Applicant's Position**

The Applicants submitted that the proposed modified mezzanine meets the 40 % requirement found in Sentence 3.2.1.1.(3). They calculated the space over the office and garage areas as being 37.5 % of the area of the addition. They argued that the area over the washroom should not be considered in the aggregate of mezzanine area, even though the joists may be capable of supporting a certain load. In their view, the washroom area is not contiguous with the what is actually being proposed as the modified mezzanine, the area over the garage and office. Further, the Applicants noted that it is not their intention to use the space over the washroom.

6. **Chief Building Official's Position**

The Respondent submitted that the aggregate of intermediate floor area, including the modified mezzanine and washroom areas is 77.6 m^2 (835 ft^2). As they noted, this figure exceeds the 40 % requirement by 2.1 %, or 4.6 m^2 (50 ft^2). According to the Respondent, the area over the washroom must be included because Sentence 3.2.1.1.(3) stipulates that the 40 %criteria is based on the aggregate calculation. Moreover, they believe that factoring in the space above the washroom in the measurement of mezzanine area is valid due to the construction of the ceiling joists. In their view, it is legitimate to expect that the Applicant will ultimately use the space over the washroom because the joists were constructed to handle such loads. They would like to see the walls of the washroom extended to the underside of the ceiling so that the space over the washroom cannot be used.

7. **Commission Ruling**

It is the decision of the Building Code Commission that a mezzanine(s) conforming to the requirements of 3.2.1.1.(3) of the Building Code is not considered a storey.

RULING

1. **The Applicant**

   Ms. Wendy Leach, home owner, has applied for a building permit under the *Building Code Act, 1992* to construct an addition on an existing, detached dwelling at 1880 Kilally Road, London, Ontario.

2. **Description of Construction/Site Description**

   The Applicants are proposing to renovate an existing 2 storey, Group C occupancy, dwelling unit with a current finished area of 573.2 m^2 (6,167.6 ft^2). The proposed construction will add a further 246.7 m^2 (2,654.5 ft^2) to the residential structure for a total finished area of 819.9 m^2 (8,822.1 ft^2) . The proposed house will contain five bedrooms and 38.5 fixtures units. The renovation will add a limited number of extra fixture units. The estimated daily design flow is 8,699 L/d.

   Regarding their sewage system, the Applicants are proposing to use the existing one for the renovated house without modification. The existing system is a conventional, gravity-based Class 4 system consisting of a 6,819 litre septic tank with a 232.3 m^2 (2,500 ft^2) leaching bed containing nine absorption trenches, comprising a total of 137.2 linear metres (450 ft). The

trenches themselves are .92 m (3 ft) deep and are filled with 19 mm (3/4 in) stone. The distribution pipe is 3 in. trade size in diameter.

The site is flat. A spring runs across the property. The soils are described as gravel and sand material with some silt. The percolation rate was measured at 2 min/cm. The topsoil is approximately 30 cm (12 in) deep.

3. **Dispute**

The issue at dispute between the Applicant and Respondent concerns whether the existing septic tank with a working capacity of 6,819 L/d serving the proposed renovated house with a total finished area of 819.9 m^2 provides sufficiency of compliance with Sentences 8.2.1.3.(1) and 8.2.2.3.(1) of the Ontario Building Code. Sentence 8.2.1.3.(1) sets out how to determine the design flows of a sewage system. According to the Table found in this provision, the calculated daily design flow for the proposed renovated house would be 8,699 L/d. Sentence 8.2.2.3.(1) stipulates that a septic tank must be designed so that it can accommodate at least twice the calculated daily design flow. This requirement would mean that the septic tank would need to have a capacity of 17,398 litres. The current, and proposed septic tank, has a volume of 6,819 litres.

4. **Provisions of the Ontario Building Code**

Sentence 8.2.1.3.Sewage System Design Flows

(1) For residential occupancies, the total daily design sanitary sewage flow shall be at least the value in Column 2 as determined from Table 8.2.1.3.A. (See Appendix A.)

Sentence 8.2.2.3.Septic Tanks

(1) The minimum working capacity of a septic tank shall not be less than twice the daily design sanitary sewage flow, except that in no case shall the working capacity of the septic tank be less than 3,600 L.

5. **Applicant's Position**

The Applicants submitted that the existing septic tank, as well as the entire sewage system, has functioned without known problems. As they noted, the soil conditions are excellent. The Applicants argued that the existing system has adequate capacity and that the sewage flows will

not change as a result of the renovation because a limited number of additional fixture units are being added.

It was their contention, in fact, that a larger tank may not function properly. They felt that the water may stagnate in the tank and would not flow into the existing leaching bed properly. They feared that this may cause harmful gases to escape, or would at least create a nuisance by the excessive odour.

In their view, the existing system, including the septic tank satisfies the intent of the OBC and would adequately serve the enlarged house.

6. **Respondent's Position**

The Respondent submitted that when considering both Sentences 8.2.1.3.(1) and 8.2.2.3.(1) of the OBC the septic tank for the proposed renovated house should have a working capacity of 17,398 litres. Since the proposal sought to allow an existing system with a 6,819 litres tank to continue to serve the new structure, they refused to issue a building permit. The Respondent also added that the system required under the Building Code would probably be too large to service the proposed house.

7. **Commission Ruling**

It is the decision of the Building Code Commission that the existing septic tank with aworking capacity of 6,819 litres serving the proposed renovated house with an addition of approximately 246.7 m^2 provides sufficiency of compliance with Article 8.2.1.3 of the Building Code provided that additional septic tank capacity of 5,000 litres is provided.

8. **Reasons**

i)The current tank capacity is only subject to modification when Clause 11.4.2.5.(3)(b) of the Building Code applies, because of the size of the addition.

ii)Articles 11.4.3.6. and 8.2.1.3. of the Ontario Building Code contain requirements for residential dwellings with an increase in finished floor area of 246.7 m^2. The design sanitary flow is increased to be 2,467 L/d requiring an additional 4,934 litres of septic tank capacity.

iii)The increased septic tank capacity to accommodate the addition as outlined in Articles 8.2.1.3 and 8.2.2.3. is significant (approx. 83% increase in capacity) and no alternative proposals or

supporting data was presented for consideration by the Commission, other than only a guest room and additional 8 plumbing fictures were to be added and that the existing system is working.

iv)It is the opinion of the Building Code Commission that the increase in septic tank capacity will improve the quality of the septic tank effluent.

Dated at Toronto this 29th day in the month of July in the year **1998** for application number **1998-37.**

Mr. Stephen Barks, Chief Building Official
Town of Innisfil, Ontario
For the Respondent

RULING

1. **The Applicant**

   Mr. Roger Howard, Planner, Rice Development Corp., has applied for a building permit under the *Building Code Act, 1992* for the construction of a new, detached dwelling unit, including an on-site sewage system at Part of Lot 7, Concession 7, Town of Innisfil, County of Simcoe, Ontario.

2. **Description of Construction/Site Description**

   The Applicant is proposing to construct a 2 storey, Group C occupancy, dwelling unit with a total finished area of 201 m^2 (2,163 ft^2). The proposed residential structure is to contain four bedrooms and twenty fixtures units. The estimated daily design flow is 2,100 litres per day.

   The subject sewage system proposes a conventional septic tank with a buried intermittent sand filter and a shallow buried trench distribution system. The system operates by clarifying the effluent by separating the liquids from the solids, as they pass from the septic tank into the sand filter. This is achieved by use of the screened pump vault found in the pump chamber of the septic tank.

The effluent is to be discharged in timed doses continually throughout the day from the septic tank to the top of the sand filter through a series of 25 mm (1 in.) diameter pressurized pipes. The pipes have perforations every 600 mm (23 5/8 in.) which are covered by an orifice shield that is designed to direct the effluent discharge downwards into the filter. The sand filter itself will be either a plywood or concrete box lined with 30 mm PVC impervious liner, installed below grade and then covered with topsoil and grass. The proposed system is designed so that the quality of effluent after filtration will be less than 10/10 BOD and total suspended solids. From the sand filter, the treated effluent will be collected in the pump basin and discharged in timed intervals to the leaching bed.

The leaching bed will be composed of two shallow buried trenches 20 metres (65 ft., 8 in.) long, placed 1.5 metres (4 ft., 11 in.) apart. The length of trench (40 metres (131 ft., 3 in.)) was arrived at by utilizing the formula of Q/75 where Q is the design sewage flow rate of 2,100 litres per day. The trenches will be approximately 300 mm (12 in.) deep and 300 mm (12 in.) wide. They will employ the chamber system design that uses a horizontally sliced 300 mm (12 in.) diameter pipe with a 25 mm (1 in.) pressurized distribution pipe running the entire length of the chamber. The distribution pipe is perforated every 600 mm (23 5/8 in.), with the perforations oriented upwards.

Both pumps in the proposed system are 1/2 horse power and are equipped with an audio-visual alarm. The timers are programmable to customize for actual water use.

While information was not provided concerning the hydrogeological conditions of the specific site in dispute (Lot 7), material was supplied regarding the larger 24.9 ha property within which the site is situated. The subject property is heavily wooded and the soils are described as variable but can generally be grouped into the following categories; silt and sand materials, silty sand material, clean sand, or sand and gravel material. The estimated percolation rates for these soil categories are; 25 to 35 min/cm approximately for the silt and sand material, 15 to 25 min/cm for the silty sand material the rate is 15 to 25 min/cm, and 60 to 15 min/cm for the clean sand or sand and gravel material. The sand and gravel areas are confined or semi-confined pockets found beneath the till. Underneath the overburden materials is limestone bedrock.

On the lower lying portions of the property there are areas where the ground water table is considered to be high, but for most of the site the water table is encountered at 1.5 metres or lower. The elevated ground water table is not an issue concerning the subject site, however. The water supply for the property is provided by piped municipal service.

The topography of the subject site, as shown on the submitted lot diagrams, is relatively flat in the north east portion. There is a fairly steep slope on the southern half of the lot, while the north western area has a gradual slope. The proposed sewage system would utilize this gradual slope in the north western quadrant, and the shallow buried trenches would be arranged so that they would be level within this slope.

3. **Dispute**

The issue at dispute between the Applicant and Respondent concerns whether the proposed residential sewage system that includes a shallow buried trench distribution system located in the Town of Innisfil may be permitted when considering Article 8.7.6.1. of the Ontario Building Code. This provision permits shallow buried trenches only in three geographic areas of Ontario, specifically the Counties of Essex and Lambton and the Municipality of Chatham-Kent.

4. **Provisions of the Ontario Building Code**

Article 8.7.6.1.Limitation on Installation

(1) Except as provided in Sentence (2), a shallow buried trench shall not be installed.

(2) A shallow buried trench may be installed in the geographic areas of the Counties of Essex and Lambton and the Municipality of Chatham-Kent. (See Appendix A.)

5. **Applicant's Position**

The Applicant submitted that the proposed sewage system will satisfy the construction requirements for shallow buried trench distribution systems found in Article 8.7.6.2. of the OBC. In their view, the proposal will meet the general health and safety standards for sewage systems found in the Code. As such, they argued that the geographic limitation on shallow buried trench distribution systems found in Article 8.7.6.1. of the OBC is unnecessary. In fact, they believe their system, with shallow buried trenches placed in the subject soil, will provide a better level of effluent treatment than required by the OBC.

Shallow buried trenches, as a system of effluent distribution, have a proven track record, the Applicants argued. The technology is not in question, it has been shown to work. As they noted, this system is recognized under the Ontario Building Code.

The Applicant stated that shallow buried trenches have existed since the 1970s and have been proven to work in many jurisdictions with a wide variety of soil types, even those with cold climates. As a result, they argued that their was no technical reason for the geographic limitation of shallow buried trenches. The decision to restrict these systems to the three designated areas was based on politics, and not on the technical competency of the systems, they asserted.

The Applicants also noted that shallow buried trenches have been permitted in many jurisdictions in Ontario outside of the three areas listed in the OBC. As examples, they submitted a recent favourable decision of the Environmental Appeal Board regarding an individual who made application for a sewage system permit under the Environmental Protection Act (EPA). The applicant in that case was seeking to install a shallow buried trench system to serve a single detached dwelling in the Regional Municipality of York. As well, a recent Ministry of Environment Certificate of Approval permitting a shallow buried trench distribution system for a dining/clubhouse facility at a Golf Course in Guelph was presented by the Applicants as further evidence of the Ontario-wide use of these systems. In this case, the subject facility was considered to have a daily design flow of 10,500 L/day and thus was still considered under the jurisdiction of the EPA.

In summation, the Applicants argued that a shallow buried trench system should be allowed at the subject site, and across Ontario. In their view, the environment, home builders and the house buying public would be better served if shallow buried trenches were permitted.

6. **Chief Building Official's Position**

The Respondent submitted that Sentence 8.7.6.1.(2) of the OBC is clear, shallow buried trenches are only permitted in the geographic areas of the Counties of Essex and Lambton and the Municipality of Lambton-Kent. The proposed shallowed buried trench system is not located in any of these areas. They noted though that the shallow buried trench system of sewage disposal does have merit. According to the Respondent, however, approval of such a system is beyond their jurisdiction.

7. **Commission Ruling**

It is the decision of the Building Code Commission that the matter of this dispute is beyond its jurisdiction as described in Section 24(1) of the Building Code Act, 1992.

8. **Reasons**

i)The powers of the Building Code Commission, outlined in Section 24(1) of the Building Code Act, 1992, are limited to resolving issues involving the interpretation of the technical requirements of the Building Code or the sufficiency of compliance with the technical requirements of the Building Code. It is the opinion of the Building Code Commission that the Building Code requirement that limits the installation of shallow buried trenches to the counties of Essex and Lambton and the municipality of Chatham-Kent (Sentence 8.7.6.1.(2)) is not a technical requirement but is an administrative requirement representing a policy decision by the Lieutenant Governor in Council to limit their installation to specific geographic locations.

While the matter of this dispute is beyond the Commission's jurisdiction, in reference to the arguments which were made, it is the Commission's opinion that the equivalency provisions of the Building Code Section 2.7 cannot be applied. Shallow buried trenches are an authorized system in specific locations under the Building Code and Section 9 of the Building Code Act, 1992 permits the use of equivalent systems only where they are not authorized by the Building Code.

ii)It is the opinion of the Building Code Commission that an amendment to the Building Code would be required to permit the installation of shallow buried trenches outside of the specified geographic locations.

City of Cambridge, Ontario
For the Respondent

RULING

1. **The Applicant**

   Mr. Bob Whitcher, Manager, Manufacturing Engineering, holds a building permit under the *Building Code Act, 1992* for the construction of an addition to an automobile manufacturing plant at 1055 Fountain Street North, Cambridge, Ontario.

2. **Description of Construction**

   The Applicant recently constructed a one storey addition to a manufacturing facility that assembles automobiles. With the addition the plant has a building area of 268,000 m^2. The building is constructed of noncombustible construction. It is fully sprinklered and is also equipped with a fire alarm system and a standpipe and hose system. The structure is classified as having a Group F - Division 3 industrial major occupancy. There are also subsidiary office spaces in the plant.

   As part of the recent construction, the Applicant installed a series of plywood platforms at eight assembly lines that serve as adjustable work stations. The platforms were made to be adjustable so that they can be positioned to safe and desirable heights as plant employees perform their

tasks. Five assembly lines have overhead conveyors that has automobiles suspended above as work is performed underneath. Three other lines are slat conveyors in which the automobiles move through the assembly process on a moving floor conveyor.

On four of the overhead assembly lines, a work pit centred under the conveyor runs the length of the assembly line. Some of the subject platforms are located in these pits, which allow for the necessary clearance of the adjustable work stations. Since the conveyors are purchased as prefabricated units, the pits and moveable platforms are useful so that the conveyors can be made more adaptable.

The area where the automobiles are assembled within the plant is open and comprises approximately 41,600 m^2.

3. **Dispute**

The issue at dispute between the Applicant and Respondent concerns whether the as constructed plywood platforms should be considered as finished flooring with concealed spaces underneath and therefore subject to Article 3.1.5.8. of the Ontario Building Code. In a building required to be of noncombustible construction, the recently constructed platforms are wood, not steel. Sentence (2) of Article 3.1.5.8. of the OB. allows a raised combustible floor in a noncombustible building as long as the concealed spaces are fire stopped. Most of the platforms exceed the height of 300 mm permitted in Article 3.1.5.8. (even exceeding 375 mm allowed in the 1997 OBC.) and some are not adequately fire stopped. If the platforms are considered to have concealed spaces beneath, they would be required to be fire stopped so that the maximum area of concealed space is limited to 10 m^2 or less according to Article 3.1.11.3. The concealed spaces would also be required to be sprinklered as per Article 3.2.5.13.

4. **Provisions of the Ontario Building Code**

Sentence 3.1.5.8.(2)Combustible Flooring Elements

(2) Wood members more than 50 mm (2 in) but not more than 300 mm (11 3/4) high applied directly to or set into a noncombustible floor slab are permitted for the support of finished flooring in a building required to be of noncombustible construction provided the concealed spaces are fire stopped in conformance with Sentence 3.1.11.3.(2).

Sentence 3.1.11.3.(2)Fire Stopping Between Nailing and Supporting Elements

(2) In a building required to be of noncombustible construction, fire stops conforming to Article 3.1.11.7. shall be provided in the concealed spaces created by the wood members permitted in Sentence 3.1.5.8.(2) so that the maximum area of a concealed space is not more than 10 m^2 (108 ft^2).

Sentence 3.2.5.13.(1)Automatic Sprinkler Systems

(1) Except as provided in Sentences (2) and (3), where a sprinkler system is required, it shall be designed, constructed, installed and tested in conformance with NFPA 13, "Installation of Sprinkler System".

5. **Applicant's Position**

The Applicant submitted that the plywood platforms should not be considered as having concealed spaces and therefore not subject to Article 3.1.5.8.

On a general level, the Applicant argued that the plywood platforms, as opposed to steel, provide more cushioning and flexibility thereby offering more comfort to assembly line workers. As well, the subject platforms are easier to adjust than similar ones made of steel, thus making them more ergonomically friendly because they can easily accommodate the height differences of the various line employees. The Applicant also indicated that the total floor space occupied by the plywood platforms is 2,865 m^2. They noted that this represents only 6.9% of the 41,600 m^2 assembly floor area.

While recognizing that the potential exists for fire to propagate in the spaces underneath the platforms, they insisted that risk to occupants is limited. The platforms are not part of ameans of egress. Workers can easily get off either side of the platforms onto the concrete floor before the smoke and heat from a potential fire under a platform could cause problems. Since the assembly area is a large, open space evacuation in such a fire could occur in reasonable time.

The Applicant also argued that fire stopping or sprinklering under the platforms is impractical because they are constantly being adjusted up or down depending on the needs of the users.

The Applicant also addressed the specifics of the different types of platforms. The first type, which covers an area of 277 m^2, are described as 1,220 mm by 2,440 mm (4 ft by 8 ft) plywood boxes that are laid side by side to create a linear platform. The boxes are 406 mm high, exceeding both the 1990 and 1997 OBC standards. Handhold slots for moving and relocation are

provided at the perimeter of each box. When positioned side by side, the handhold slots line up from one box to the next. The Applicant argues that these box-type platforms should be allowed because they are similar to wood flooring allowed under Article 3.1.5.8. with the exception that they are slightly higher which does not appreciably increase the associated hazards. They also note that there is no potential fire sources such as motors, cabling, etc. contained in these platforms.

The second type of platform is also a box type and it covers 447 m^2. These boxes are less than 375 mm in height, however, some have a steel framed, prefabricated motor driven conveyor belt beneath. The electric motors below some platforms are the potential ignition points, nevertheless, these have been equipped with a pinch point protection system that provides for metal flaps that cover the space between the edge of the conveyor belt and the box they sit in. These boxes have hinged access hatches to provide quick fire fighting access. The Applicant is recommending that the handhold holes be fire stopped in these platforms.

The last type, at 2,141 m^2, occupies nearly 75 % of the platform area. Located in the concrete pits found at the overhead assembly lines, these platforms are 406 mm high, and contain a similar conveyor mechanism (as described above) underneath. This type of platform is not fire stopped under the walking surface. As the Applicant argued, this platform type does meet the intent of Article 3.1.5.8. since it does provide for some inhibiting of the spread of fire in a concealed space because the pit areas themselves are limited in length. As well, it allows occupants an easy opportunity to dismount onto a concrete floor in an open space which, the Applicant stated, provides an immediate and safe access to a means of egress.

Lastly, the Applicant contended that the plywood platforms installed in the manufacturing facility should be viewed more as an adjustable tool and not as a fixed flooring system and should therefore not be required to fire stop and sprinkler below the plywood platforms.

6. **Chief Building Official's Position**

The Respondent submitted that the installed combustible platforms do not meet the requirements of the OBC, specifically Sentences 3.1.5.8.(2), 3.1.11.3.(2) and 3.2.5.13.(1).

The Respondents argued that there were three aspects of the platforms that were not complying with the Building Code. The first issue is that some of the platforms are too high. Applying the 1990 OBC standards, they noted that the maximum height permitted in Sentence 3.1.5.8.(2) was 300 mm (11 3/4 in). Two of the three platform types exceed this height.

The second issue they raised was that was that none of the platforms were fire stopped in accordance with Sentence 3.1.11.3.(2). The Respondents also added that the maximum area of any single concealed space be limited to 10 m^2 (108 ft^2).

The requirement for sprinklering the concealed spaces found in Sentence 3.2.5.13.(1) was the third issue brought forward by the Respondent. In their view, the platforms should be built to conform with NFPA 13 standards for sprinklering a concealed spaces found in combustible construction. They noted that none of the platforms are currently sprinklered.

7. **Commission Ruling**

It is the decision of the Building Code Commission that the combustible platforms do not provide sufficiency of compliance with the requirements of the Building Code.

8. **Reasons**

i)It is the opinion of the Building Code Commission that the platforms are not considered fixtures and are part of the building.

Ms. Cveta Prgin, Building Engineer
Oshawa, Ontario
For the Respondent

RULING

1. **The Applicant**

   Mr. Mohammad Abhary, Vice President, Arya Investments Corp. holds a building permit under the *Building Code Act, 1992* for a new multiple store retail plaza at 1276 - 1288 Ritson Road North, Oshawa, Ontario.

2. **Description of Construction**

   The Applicant recently constructed a one storey, 1,294.6 m^2 retail plaza which could contain a maximum of twelve units. Each unit is approximately 107 m^2. Currently some of the units have been combined into larger stores. The building is constructed of noncombustible construction. It is not equipped with a fire alarm system nor a sprinkler system. The structure is classified as having a Group E - mercantile major occupancy.

   One of the retail outlets combines four units for a floor area of roughly 428 m^2 and is leased to a dollar store. This store is equipped with only one washroom for both sexes. This washroom is handicapped accessible. The maximum number of employees in the dollar store at any time is three persons. The other stores are provided with their own washroom facilities.

3. **Dispute**

The issue at dispute between the Applicant and Respondent is whether the current provision of one water closet in a 428 m^2 retail store provides sufficiency of compliance with Clause 3.6.4.2.(25)(b) of the Ontario Building Code. This provision stipulates that a mercantile occupancy under certain conditions can be allowed to have only one water closet. One of the conditions is that the Group E occupancy is less than 300 m^2.

4. Provisions of the Ontario Building Code

Clause 3.6.4.2.(25)Sanitary Facilities

Not more than 1 water closet to serve both sexes need be provided in

(b)a Group E or F occupancy,

(i)having an occupant load not exceeding 9 persons, or

(ii)where the sum of the floor areas, excluding basements, does not exceed 300 m^2 (3230 ft^2).

5. **Applicant's Position**

The Applicant submitted that the current washroom facilities are adequate for the number of employees. He further indicated that the lessor has informed him that at no time has any patron requested to use their washroom. In his view, OBC clause 3.6.4.2.(25) is too onerous for a small sized store.

6. **Chief Building Official's Position**

The Respondent submitted that the as constructed retail plaza with only one water closet does not provide sufficiency of compliance with the Ontario Building Code. They argued that the floor area of the Dollar Store, at 428 m^2, clearly exceeds the 300 m^2 maximum that allows one washroom in Clause 3.6.4.2.(25)(b). As they note, the Applicant freely concedes this point. Further, they calculate that using a rate of 3.7 persons per m^2 for mercantile uses as found in table 3.1.16.A. translates into an occupant load of 115 persons for the Dollar Store, which is obviously far in excess of the 9 persons allowed in Clause 3.6.4.2.(25)(b).

Having not qualified under Clause 3.6.4.2.(25)(b), the Respondents instead indicated that the Dollar Store should be subject to Clause 3.6.4.2.(24)(b). This provision requires that one water closet be provided in a Group E occupancy for each sex where the sum of the floor area is less than 600 m^2.

Finally, the Respondents advised that the plans submitted for a permit showed two washrooms, but only one was constructed.

7. **Commission Ruling**

It is the decision of the Building Code Commission that the 428 m^2 retail store equipped with a single handicapped accessible washroom does not provide sufficiency of compliance with Subclause 3.6.4.2.(25)(b) (ii) of the Building Code.

Reasons

i)No alternative measures were provided for sufficiency of compliance.

ii)No other public washrooms are provided in the building complex.

iii)The occupant load and building area both exceed the requirements of Sentence 3.6.4.2.(25)

Dated at Toronto this 4th day in the month of June in the year **1998** for application number **1998-23.**

BCC Ruling No. 98-24-629

BUILDING CODE COMMISSION DECISION ON B.C.C. #98-24-629

RULING

1. **The Applicant**

   Ms. Daniela Lepre, Project Coordinator, Leaside Green Inc., has applied for a building permit under the *Building Code Act, 1992* to construct an 82 unit, low rise, residential condominium townhouse project known as Leaside Green, 15 Overlea Blvd, Toronto (East York), Ontario.

2. **Description of Construction**

   The Applicant proposes to construct an 82 unit, low rise, townhouse condominium project. The individual units are clustered together into several larger blocks. The total building area of each of the blocks is less than 600 m^2 (6,460 ft^2). The units are proposed to be constructed of combustible construction, with a 1 hour fire separation between units. The blocks will not equipped with a standpipe and hose system nor a sprinkler system. The individual units are to be provided with a fire alarm and smoke detection system. The buildings are classified as Group C - residential occupancy.

   There are numerous different unit types designed for this project. Each of the blocks are a combination of the different unit designs. Four of the Applicant's unit designs contain

mezzanines on the third floor. In particular, the mezzanines are found in the Ab, C, D and E unit types, accounting for sixteen units in total. These units are combined in the larger blocks with non-mezzanine units. The sizes of the mezzanines ranges from 22.9 m^2 (246 ft^2) to 29.3 m^2 (315 ft^2).

3. **Dispute**

The issue at dispute between the Applicant and Respondent is whether the proposed mezzanines, as designed, in sixteen units within the project comply with Sentence 9.10.4.1.(2) of the Ontario Building Code. This provision allows a mezzanine to not be considered as a storey under certain conditions. Complying with Sentence 9.10.4.1.(2) is significant for the construction of the blocks containing mezzanine units since if they are instead defined as floors then the units would be considered as having four floors of building height, meaning they would be subject to the construction requirements found in Part 3 of the OBC. The four floor units would therefore be required, for example, to be constructed of non-combustible construction, or if combustible construction is used then the units must be sprinklered and the separations between the four and three floor units must be two hour rated fire walls.

As a result of this dispute, the Applicant elected to submit plans for a permit showing sprinklers throughout the mezzanine units with two hour fire walls. They are now seeking clarification on the mezzanine issue and wish to revise their building permit to delete the sprinklers and fire walls. The municipality has issued a partial building permit for the blocks that do not contain units with mezzanines, or fourth floors.

4. **Provisions of the Ontario Building Code**

Sentence 9.10.4.1(2)Mezzanines not considered as storeys

(2) Mezzanines shall not be considered as storeys for the purpose of determining building height where they occupy an aggregate area not exceeding 40 per cent of the area of the room or the storey in which they are located provided the space above the mezzanine floor has have (sic) no visual obstructions more than 1 070 mm (3 ft 6 in) above such floors.

5. **Applicant's Position**

The Applicant submitted that the proposed mezzanines should not be defined as a fourth storey of building height. In her view, the mezzanines comply with the conditions found in Sentence

9.10.4.1.(2). As the Applicant argued, with the mezzanines ranging in size from 22.9 m^2 (246 ft^2) to 29.3 m^2 (315 ft^2) none exceed 40 % of the third floor areas within their units. She also indicated that the mezzanines have no visual obstructions more than 1 070 mm (3 ft, 6 in). The Applicant argued that the OBC nor the Guide to the OBC provide any direction on how open in terms of design a mezzanine must be in order to qualify as a mezzanine. As a result, she asserted that the mezzanines are not an additional storey, thus the mezzanine units should be subject to the requirements of Part 9 of the Code.

To underscore her view, the Applicant compared the Leaside Green project with a similar one in the former City of Toronto that also had a "fourth level" in some of the units. That project's fourth levels were considered as mezzanines on the third floors. The Applicant also provided two other examples of joined townhouse condominium blocks that were built according to Part 9, but apparently had four levels.

The Applicant also submitted three separate options for providing sufficiency of compliance with the Part 3 provisions of the OBC if the Building Code Commission were to interpret the subject units as having four floors of building height. Nevertheless, the Applicant still maintained that the mezzanines, as designed, should be considered mezzanines.

6. **Chief Building Official's Position**

The Respondent submitted that the proposed mezzanines should be considered as a fourth storey of building height. In their view, the subject mezzanines have a clearly designed floor structure between the third and fourth levels. The mezzanines do not act as intermediate floor levels, nor can they be considered interior balconies. As they indicated, the proposed mezzanines do not meet the OBC definition of mezzanines. From this interpretation that the subject units are four storeys, it is their opinion that the Part 3 provisions of the Code must be applied.

7. **Commission Ruling**

It is the decision of the Building Code Commission that the proposed construction does not demonstrate sufficiency of compliance with the requirements of the Building Code and must conform to the requirements of Part 3.

8. **Reasons**

i)The proposed mezzanine are considered storeys since they are not an intermediate floor assemblies between the floor and ceiling of a storey.

ii)The proposed mezzanines are considered storeys since visual obstructions exist in the space more than 1070 mm (3 ft 6 in) above the mezzanine floors.

RULING

1. **The Applicant**

   Mr. George Simeonoff, President-Manager, Everstrong Floors and Walls Ltd., has been issued an order to comply under the *Building Code Act, 1992* to insulate a concrete floor assembly which separates a garage from a studio above thereby bringing the floor into conformity with Article 9.25.2.7. of the Ontario Building Code at 1497 Bancroft Drive, Mississauga, Ontario.

2. **Description of Construction**

   The building in dispute is a two-storey, single-detached residential structure and is the home of Mr. and Mrs. Peter Miller. It has a building area of 306.7 m^2 (3,300 ft^2).

   The concrete floor assembly in question separates an unheated double car garage from a studio above and is uninsulated. Several loops of hydronic piping are embedded in the underside of the subject floor assembly which provides a certain level of heat in the garage and heat that radiates throughout the floor. (The current owner contends that the average garage temperature is 12.8^{o}C

(55°F)). Within the studio space the concrete floor has been finished with tiles. The rest of the building is heated by a conventional forced air system.

The garage walls are constructed (from exterior to interior) of a stucco coating on 45 mm (1 3/4 in) precast concrete on 38 mm (1 1/2 in) rigid insulation on 9.5 mm (3/8 in) exterior plywood supported by 38 by 135 mm (2 by 6 in) wood framing studs fini shed with 13 mm (1/2 in) gypsum board. The garage has an automatic, steel door.

3. **Dispute**

The issue at dispute between the Applicant and Respondent is whether the subject concrete floor assembly as constructed without insulation provides sufficiency with Articles 9.25.2.1. and 9.25.2.7. of the Ontario Building Code. Article 9.25.2.1. sets out the general requirement that walls, floors and ceilings that separate heated space from non-heated space must be provided with insulation. Article 9.25.2.7., in particular Sentence (1), sets out the specific R values required for the various building elements exposed to unheated space. As Table 9.25.2.A. of Article 9.25.2.7. stipulates, a floor, other than a slab-on-ground, is required to provide insulation of RSI 4.4 (R25).

Since the hydronic tubing on the underside of the concrete slab provides a certain amount of heat in the garage the Applicant considers the garage to be heated space. The municipality on the other hand considers the garage as unheated. As such, they believe that insulation should be installed to bring the disputed floor into conformity with the OBC.

There also appears to be a discrepancy involving the plan review and inspection of the building regarding hydronic heating system. It seems the house was given approval based on the conventional heating system with insulation on the underside of the garage ceiling slab. A separate application was made later for the hydronic heating system. The Applicant contended that the hydronic system substituted for the insulation. The municipality expected that the insulation would be installed along with the hydronic system.

4. **Provisions of the Ontario Building Code**

Article 9.25.2.1. Required Insulation

All walls, ceilings and floors separating heated space from unheated space, the exterior air or the exterior soil shall be provided with sufficient thermal insulation to prevent moisture

condensation on their room side during the winter and to ensure comfortable conditions for the occupants.

Article 9.25.2.7. Minimum Thermal Resistance

(1) Except as permitted in Sentences (2), (3) and (4) the minimum thermal resistance of insulation shall conform to Table 9.25.2.A.

5. **Applicant's Position**

The Applicant submitted that the concrete floor slab should not be required to provide any insulation whatsoever. In his view, the hydronic heating system, which offers not only heating but also a level of insulation between heated and unheated spaces , provides sufficiency of compliance with Articles 9.25.2.1. and 9.25.2.7. Although the Applicant does not consider the garage to be heated space, he did indicate that its average annual temperature was 12.8^{o}C (55^{o}F). He argued this was primarily because of the hydronic heating system, which he also noted contributes to the heating in the studio above. The temperature in the studio above the garage is maintained at a comfortable 21.1 to 23.8^{o}C (70 to 75^{o}F). Further, the tiles in the studio are always appropriately warmed, he claimed.

In the Applicant's opinion, insulation is not necessary because the concrete slab is warm already. It is a source of heat itself, he argued, that does not need insulation. The hydronic heating system acts as a layer of insulation in that serves to mitigate the cooler temperatures of the garage with respect to the heated studio above.

The Applicant noted that the subject building was being constructed as a model to feature "Precast Concrete and Wood Composite Walls" and "Suspended Concrete Composite Floors" with hydronic heat radiators. This demonstration house was given approval by the municipality except for the hydronic system, which required a separate application. As the Applicant noted, hydronic systems are not found within the Code. To keep the projectmoving, it was decided to apply for a conventional forced air heating system. During construction, the Applicant proposed a revision to the heating plan to include the hydronic system. He indicated that nearly eight to ten months past before the municipality objected to the hydronic system and the lack of insulation. By this time the house had been sold and the current occupants were surprised to hear of the municipality's concerns. The Applicant provided a letter from the owners stating that they are very happy with the hydronic heating system.

For these reasons, the Applicant was of the opinion that the R25 insulation was not required on the underside of the garage ceiling.

6. **Chief Building Official's Position**

The Respondent submitted that the subject floor assembly must be provided with R25 insulation as per Table 9.25.2.A. of the Ontario Building Code. In their view, the hydronic system is just a supplementary heating system designed only to temper cold floors. It is not a substitute heating system, they argued. As a result, in the Respondent's opinion the garage is unheated space. Since the garage in their view is not heated it follows then that insulation as per Table 9.25.2.A. is required. Further, they were clearly of the view that the hydronic system cannot act as a replacement to insulation.

Regarding the plans examination and inspection, the Respondent noted that while the hydronic system had been permitted, the requirement for insulation had never been waived. As well, the need for insulation as per the approved drawings was indicated to the contractor several times during construction.

Finally, the Respondent offered the Applicant an alternative method of complying with the provisions of the OBC. They stated that they would be willing to eliminate the insulation requirement if heat loss calculations were conducted on the garage and an approved heating system be designed and provided in the garage that would satisfy the heat loss conditions. In effect, the Applicant would be required to make the garage truly heated space, thus eliminating the need for insulation.

7. **Commission Ruling**

It is the decision of the Building Code Commission that the garage ceiling demonstrates sufficiency of compliance with the requirements of the Building Code.

8. **Reasons**

1)A number of measures have been installed that provide additional energy savings including:

a)RSI 1.76 (R7.5) insulation in the garage walls.

b)RSI 4.84 (R27.5) insulation in the house walls.

c)A high efficiency furnace.

d)A heat recovery ventilator.

2)Insulating the garage ceiling is impractical given the intent of the in-floor hydronic heating system to keep the floor above warm and to supply low grade heat to the garage.

3)The garage ceiling slab is heated with a heating system independent from that of the house.

RULING

1. **The Applicant**

   Mr. Thomas Phillips, Owner, Part Lot 18, Concession 1, has been issued an order to comply under the *Building Code Act, 1992* to bring a floor joist system of a farm building into conformity with Article 9.40.3.3. of the Ontario Building Code at Part Lot 18, Concession 1, Carden Township, Ontario.

2. **Description of Construction**

   The Applicant's property contains several buildings, including a two storey, 12.2 by 24.4 m (40 by 80 ft) steel arch quonset hut structure that has a building area of 297.4 m^2 (3,200 ft^2). The structure is constructed of combustible construction on the interior with a noncombustible exterior shell. It is classified as a Farm Building under the OBC.

   The quonset hut is divided into two portions, with the front, or southern, half containing a 118.9 m^2 (1,280 ft^2) second storey. The lower floor contains laundry, kitchen and washroom facilities. The upper level is used as an open storage area. The rear portion of the quonset hut is used as a garage.

The second storey floor assembly of the west portion of the quonset hut is constructed of 38 by 235 mm (2 by 10 in) spruce joists at 300 mm (12 in) on centre and includes both strapping and bridging. The east portion of this floor assembly is construc ted of engineered 235 mm (10 in) TJI joists at 300 mm (12 in) on centre. The spans of these two floor assemblies are 4.52 m (14 ft, 10 in) and 5.74 m (18 ft, 10 in) respectively. The latter floor assembly is not in dispute.

3. **Dispute**

The issue at dispute between the Applicant and Respondent is whether the as built floor joists in the western portion of the second storey provides sufficiency of compliance with Article 9.40.3.3. of the Ontario Building Code. This provision stipulates that the building in question may be designed according to Tables 9.40.3.K. to 9.40.3.T. In particular, Tables 9.40.3.M. and 9.40.3.N. set out the standards for floor joist construction for intermittent and continuous loads respectively.

For intermittent loads, applying Table 9.40.3.M. to the building at hand, 38 by 235 mm (2 by 10 in) joists are required, however, Table 9.40.3.N. stipulates that continuous loads in this situation are required to be supported by 38 by 286 mm (2 by 12 in) joists. Further, as a farm building, the Canadian Farm Building Code also applies to this structure. Article 2.2.1.5. of the CFBC requires that floors supporting stored products, as is the case in this building, bedesigned for their loads according to their intended use, but must not be less than 5.0 kPa. If the joists are found to be over spanned additional supports would be required.

The Applicant previously adjusted the spacing of the subject joists from 400 mm (16 in) on centre to their current 300 mm (12 in) on centre. He also added strapping between the joists to improve their stability. This did not resolve the over spanning issue as far as the municipality was concerned. There also seems to be a discrepancy regarding the actual length of span in question. The Applicant contended the spans is 4.52 m (14 ft, 10 in), whereas the Respondent measured it at 4.65 m (15 ft, 3 in) .

4. **Provisions of the Ontario Building Code**

Article 9.40.3.3. Structural Requirements - Spans

In a farm building of low human occupancy, the spans of wood joists, rafters, lintels and beams may conform to the spans shown in Tables 9.40.3.K. to 9.40.3.T. for the live loads shown in the Tables.

5. **Applicant's Position**

The Applicant submitted that the 38 by 235 mm spruce joists with strapping and bridging provides sufficient structural support for the intended load to span 4.52 m. He argued that due to the limited nature of floor to ceiling space on the second floor of the arched quonset hut the floor assembly in question would never be required to support 5.0 kPa of live load. Simply put, there is not enough space above the floor to create 5.0 kPa worth of loading. In fact, the Applicant indicated that the western portion of the second floor would not be used for the storage of farm or agricultural materials. Instead, he indicated that it would be used more as an accessible attic similar to how one might use an attic in a house. Or if his pending rezoning to change the southern half of the subject building to residential gets approved, this area could be used as living quarters.

As a result, the Applicant pointed to Article 9.23.4.1., specifically Tables A-1 and A-2 which show that 38 by 235 mm spruce joists at 300 mm on centre are permitted to span to a maximum of 4.60 m. At 4.52 m, as measured by the Applicant, the span in question is acceptable. The Applicant asserted therefore that no additional support was needed for the floor joists.

6. **Chief Building Official's Position**

The Respondent submitted that the as built floor joist framing does not comply with Article 9.40.3.3. of the Ontario Building Code, specifically Tables 9.40.3.M. or 9.40.3.N. The Respondent rejected the Applicant's proposed use of the second floor space as an attic orfuture living quarters. In fact, the Respondent indicated that the municipality had previously ordered the removal of residential furnishings and appliances from the space. He noted that the current zoning of the building was agricultural not residential, and that the appropriate OBC standards for the current occupancy of the building should be applied.

Allowing that the storage of materials in this space could be considered intermittent and not continuous, the Respondent indicated that the joists must comply with Table 9.40.3.M. Further, he stressed that as a farm building Article 2.2.1.5. of the Canadian Farm Building Code applies, meaning that the minimum design load for this storage area must be at least 5.0 kPa.

When considering the 5.0 kPa loading minimum and applying Table 9.40.3.M., the Respondent determined that 38 by 286 mm (2 by 12 in) joists are required in the subject floor assembly. Since the floor was constructed with only 38 by 235 mm joists, the Respondent was of the view that additional support of the floor assembly was necessary.

7. **Commission Ruling**

It is the decision of the Building Code Commission that the floor system demonstrates sufficiency of compliance with the requirements of the Building Code provided:

i)a kneewall is constructed along the exterior perimeter of the quonset hut between the roof and floor of the second storey; and

ii)floor sheathing is not installed on the floor system between the kneewall and building perimeter; and

iii)an engineer's report, acceptable to the municipality, is carried out verifying the floor system is capable of supporting at least 5 kPa load over the revised storage area.

8. **Reasons**

i)The kneewall will limit the floor area available for storage.

ii)Omitting floor sheathing on the floor area beyond the kneewall will further restrict the ability to store material on the floor system.

iii)Calculations will be produced to verify the floor system is able to support the required minimum loads.

RULING

1. **The Applicant**

   Mr. Keith McEwen, President, Keith McEwen Associated Ltd. received a building permit under the *Building Code Act, 1992* to construct an air-supported addition to an existing one storey office building at the Guelph Sports Dome, 550 Imperial Road North, Guelph, Ontario.

2. **Description of Construction**

   The Applicant recently constructed a new air-supported structure, known as the Guelph Sports Dome, as an addition to an existing one storey office building. The addition is intended to accommodate a two-tiered indoor golf range and three soccer fields. The enlarged building, including addition, has a total building area of 3,132.4 m^2 and is one storey in building height, with the highest point measured at 15.24 metres. The occupant load is approximately 160 persons.

The air-supported, fabric-covered, sports dome has a building area of 3,076 m^2. Also included in the recent addition is a 53.5 m^2 air-lock storage area and a 2.9 m^2 air-lock entrance. A 1 hour fire separation was provided where the air-supported addition connects to the existing office building. The addition is constructed of combustible construction. Fire department access is provided on the north side of the addition.

The addition is classified as a Group A, Division 2 - sports/entertainment assembly occupancy. As currently built, the air-supported structure is not equipped with a fire alarm system, a sprinkler system, nor a standpipe and hose system.

The existing office building is also constructed of combustible construction. It has a building area of 187.4 m^2 and has fire department access on its east side. It is classified as a Group D - Business occupancy

The permit application for the air-supported structure was made under the requirements of the 1997 OBC.

3. **Dispute**

There are three issues at dispute between the Applicant and Respondent. The first issue is whether the air-supported structure should be equipped with a standpipe and hose system as per Sentence 3.2.9.1.(1). This provision stipulates that a standpipe and hose system must be installed in a single storey building containing an assembly occupancy that is 2,500 m^2 or larger. Sentence 3.2.9.1.(1) does allow air-supported structures an exemption from this requirement.

The second issue is whether the two-tiered golf driving range, which represents a mezzanineapproximately 4.6 % of the floor area, must be provided with a 1 hour fire-resistance rating. Sentence 3.13.2.2.(5) of the OBC requires that interior mezzanines within air-supported structures must meet the construction requirements found in Subsection 3.2.2., specifically Article 3.2.2.24. This provision states that the mezzanine must be constructed of noncombustible construction, including its supporting members, and have a fire-resistance rating of at least one hour. The noncombustible requirements of this provision also applies to the air-lock facilities, the storage and entrance areas.

The third issue is whether the air-lock vehicle/storage and entrance areas can be attached to the main portion of the air-supported structure without providing a 1 hour fire separation at the connection. Sentence 3.13.2.3.(4) permits an air-supported structure to be connected to another

building if the building is less than 200 m^2 and a 1 hour fire separation is provided at the connection.

4. **Provisions of the Ontario Building Code**

Sentence 3.2.9.1.(1)Where Required

(1) Except as provided in Sentences (4) to (7), a standpipe system shall be installed in every building that

a) is more than 3 storeys in building height,

b)is more than 14 m (45 ft 11 in) high measured between grade and the ceiling of the top storey, or

c)is not more than 14 m (45 ft) 11 in) high measured between grade and the ceiling of the top storey but has a building area exceeding the area shown in Table 3.2.9.1. for the applicable building height if the building is not sprinklered.

Sentence 3.13.2.2.(5)Interior Construction

(5) Interior construction contained within air-supported structures must meet the construction requirements of Articles 3.2.2.20 to 3.2.2.83.

Sentence 3.13.2.3.(4)Connection to Adjacent Building

(4) An air-supported structure is permitted to be attached to another building provided the building to which it is attached.

a)has a building area not more than 200 m (2,150 ft).

b)conforms to the requirements of other Parts of the Code based on the building area of the attached building, and

c)is sprinklered or separated from the air-supported structure by a fire separation having a fire-resistance rating of not less than 1 h.

5. **Applicant's Position**

By way of general comments, the Applicant indicated that the design of the subject air-supported structure complies with all other relevant provisions in Part 3 of the OBC, save for the disputed areas. This includes the clearance from adjacent properties and flammable material and vegetation, structural design and flame-resistance. The Applicant noted that the fabric covering the proposed addition meets the CAN/ULC S-109-M standard and is in fact self-extinguishing, thereby unable to support combustion.

The Applicant also noted that the fire separation between the addition and the existing office area is not at issue since, as a separate building, they concur that a 1 hour fire separation is required. Further, the provision of egress from the sports facility far exceeds the Code requirements, the Applicant contended. This is due to the fact that the exits provided are sufficient for 650 people, although the occupant load is only 160 persons (as calculated by the Respondent) and that the 30 metre travel distance requirements are easily met. The evacuation time would therefore be faster than that required in the Code. Also noted by the Applicant was that there is little visual obstruction in the building that could hide potentially dangerous situations and that the sports facility has on-site staff to supervise in case of an emergency.

Moreover, the life safety of the building is currently being enhanced by the incorporation of an early warning system to detect sudden changes in pressure. This is being done by linking pressure gauges into the 24 hour monitored security system. This is in addition to the already in place emergency power system.

Regarding the first issue, the Applicant submitted that the provision of a standpipe and hose system in the air-supported building would be of questionable value to the responding fire department. They note that the manufacturer of the subject structure recommends that fire fighting activities occur from the exterior using street hydrants. In the case of the subject facility, a hydrant is located directly across the municipal street. The Applicant also noted that the addition has very little combustible load, virtually no sources of ignition, and is supplied with several portable fire extinguishers

On the issue of the construction requirements for the mezzanine, the Applicant recognized that Sentence 3.13.2.2.(3) exempts air-supported structures from most of the construction requirements found in Subsection 3.2.2., with the exception of interior construction, which includes the mezzanine. The Applicant, however, argued that the as built mezzanine provides an acceptable level of life safety without providing the 1 hour fire resistance rating. They described the construction of the mezzanine as being primarily of noncombustible elements. (The

construction of the mezzanine is as follows; 25 oz astro grass is laid on 5/8 in plywood on noncombustible insulation on a 1 in steel deck which is supported by a structure of structural steel.) They also argued that the construction of the mezzanine does not leave the combustible exposed. In their view, this represents a less hazardous situation than combustible finished flooring which is allowed in noncombustible construction, or concealed spaces created by combustible nailing.

Further, the Applicant pointed out that the mezzanine is a stand alone structure that is open on all four sides. This allows excellent visibility of the sports facility thus allowing occupants ample warning time to evacuate. Also, with four open sides occupants would not be trapped on the mezzanine. While the Respondents have assigned the mezzanine an occupant load of 60, in the Applicant's view, since there are only 11 driving stations the actual load is and will be much lower.

The Applicants indicated that previous Building Code Commission have recognized similar construction and occupant use for mezzanines. They discussed as well that the mezzanine complies with the OBC regarding egress, guards and rails, emergency lighting and structural design.

Regarding the connection to the adjacent vehicle/storage air-lock and entrance air-lock, the Applicant is of the opinion that these areas are not separate buildings, but are instead subsidiary elements, part of the overall air-supported structure. It follows, they argued, that Sentence 3.13.2.3.(4) with its 1 hour fire separation requirements does not apply. As the Applicant noted the vehicle air-lock is provided so that a vehicle can enter the building or be stored with other material that relates to the operation of the sports facility while still maintaining operating pressure and the entrance enclosure serves to protect the revolving door lock from the weather. These two areas have no occupancy in and of themselves, they are ancillary to the main area of the sports dome.

The Applicant did not view these connections as part of the interior construction that is required to be noncombustible. Rather, they considered the subject connections as part of the building that is allowed to be exempt from the construction requirements found in Subsection 3.2.3. Besides, construction of an internal fire separation at the vehicle air-lock would provide minimal benefit since the exterior fabric walls of the sports dome area meet those of the vehicle air-lock area without separation. Nevertheless, the Applicant stated that they were willing to finish the interior of the vehicle air-lock with gypsum wallboard.

For the above described reasons, the Applicant is of the opinion that the proposed design of the air-supported structure provides sufficiency of compliance with the relevant provisions of the Building Code.

6. **Chief Building Official's Position**

The Respondent submitted that Subsection 3.2.9. of the OBC is clear in its requirement of a standpipe and hose system. As they note, the building has an assembly occupancy, is a single storey and is greater than 2,500 m^2, which according to Sentence 3.2.9.1.(1) means that a standpipe and hose system is required.

Concerning the mezzanine, the Respondent cited Sentence 3.13.2.2.(5) which refers to the construction requirements of Subsection 3.2.2., which for the subject building means that the mezzanine must be built with noncombustible construction and have a 1 hour fire-resistance rating for the mezzanine and its structural members.

In the Respondent's view, the two ancillary areas, namely the vehicle air-lock and the entrance air-lock, should be treated as separate buildings and must therefore provide a 1 hour fire separation between these two areas and the sports dome area. They argued that the air-lock areas are more appropriately viewed as additions to the sports dome which are both combustible construction and are built with different materials than the sports dome area. The Respondent noted that the air-lock areas could opt for sprinklering as an alternative to providing the 1 hour fire separation.

As a result of the above discussion, the respondent did not believe that the sports dome, as constructed, provides sufficiency of compliance with the applicable OBC provisions.

7. **Commission Ruling**

It is the decision of the Building Code Commission that the air supported structure connected to the single storey office building provides sufficiency of compliance with Articles 3.2.9.1., 3.13.2.2., and 3.13.2.3. of the 1997 Building Code provided that:

i)The occupant load is limited to 160 persons and a sign limiting occupancy is posted in accordance with Sentence 3.1.16.1.(2) of the Building Code.

ii)The interior of the vehicle air-lock is protected with drywall material or equivalent to provide a 45 minute fire-resistance rating and the over head door between the vehicle air-lock and the air-supported structure is of noncombustible construction.

iii)Monitored smoke detection devices are installed within the structure or within the air handling system and connected to the existing security system.

8. **Reasons**

i)This structure is in the same location and is the same approximate size as former air-supported structures on the site and is using the same foundation base.

ii)The main entrance and air-lock will be protected combustible construction having a 3/4 hour fire-resistance rating.

iii)The mezzanine structure is noncombustible.

iv)The building occupant load is limited to 160 persons.

v)Early warning detection is installed and connected to a central monitoring agency.

Dated at Toronto this 6th day in the month of May in the year 1998 for application number 1998-17.

BCC Ruling No. 98-20-625

BUILDING CODE COMMISSION DECISION ON B.C.C. #98-20-625

IN THE MATTER OF Subsection 24 (1) of the *Building Code Act, 1992*.

AND IN THE MATTER OF Clauses 3.2.8.2.(9)(c), 3.2.8.2.(9)(e) and 3.2.8.2.(9)(f) of Regulation 61, as amended by O. Reg. 400/91, 158/93, 160/93, 383/94, 20/95 and 395/96 (the "Ontario Building Code").

AND IN THE MATTER OF an application by Mr. Roul Martjak, Senior Clerk of Work, Toronto District School Board (Formerly York Board of Education), Toronto (York), Ontario for the resolution of a dispute with Mr. Bruce Ashton, Chief Building Official, City of Toronto (York), Ontario to determine whether the unenclosed walkway in the proposed two storey school structure provides sufficiency of compliance with Clauses 3.2.8.2.(9)(c), 3.2.8.2.(9)(e) and 3.2.8.2.(9)(f) of the Ontario Building Code at The Clouston Schools, 100 Sidney Belsey Crescent, Toronto (York), Ontario.

RULING

1. **The Applicant**

   Mr. Roul Martjak, Senior Clerk of Work, has applied for a building permit under the *Building Code Act, 1992* to construct a new, two-storey, elementary and middle school at 100 Belsey Crescent, Toronto (York), Ontario.

2. **Description of Construction**

   The Applicant proposes to construct a new, two storey school with two wings, the east wing serving as an elementary school and the west wing as a middle school. The wings are joined by a large general purpose room and a solarium, which includes a second floor walkway linking the two schools. The proposed walkway is unenclosed, thus acting essentially as a second storey bridge spanning the main entrance lobby, or solarium. It also overlooks the adjacent general purpose room. The walkway is necessary because it allows both schools to access the exit stairs provided at the south end of the second floor corridors. Without the walkway, these corridors would otherwise terminate at their southern end.

The bridge itself will be 30 metres long, 4 metres wide, and 3.8 metres above the floor of the solarium. The floor of the bridge is proposed to have a 1 hour fire resistance-rating, as measured from the underside. Each end of the walkway is fire separated from the second floor with a 30 minute rating.

The proposed building has a building area of 5,990 m^2. It is to be built of noncombustible construction, with the exception of the heavy timber proposed for the roof area over the general purpose room and the solarium. The building is equipped with a fire alarm and detection system, an automatic sprinkler system and is considered to face one street. The structure is classified as a Group A, Division 2, school occupancy.

3. **Dispute**

The issue at dispute between the Applicant and Respondent is whether the proposed walkway is allowed to be unenclosed under the 1990 Ontario Building Code, in particular Sentence 3.2.8.2.(9). To elimate dead-end corridors. This provision allows interconnected floor space under certain conditions, one of which is that floor openings adjacent to a corridor must terminate at a fire separation rated at 30 minutes. If the bridge is viewed as a part of the corridor system, then 3.2.8.2.(9) applies and a 30 minute fire separation extending from the floor of the walkway to the underside of the ceiling above must be provided. However, if the bridge can be considered as a mezzanine, then 3.2.8.2.(9) does not apply and no fire separation is required.

4. **Provisions of the Ontario Building Code**

Sentence 3.2.8.2.(9)Interconnected Floor Space in Schools

(c)the portions of the upper floor area that do not terminate at an exterior wall, a firewall or a vertical shaft shall terminate at a vertical fire separation extending from the floor assembly to the underside of the floor or roof assembly above,

(e)where a corridor is located immediately adjacent to the fire separation required in Clause (c), the fire separation shall have a fire-resistance rating of not less than 30 min, and

(f)where a portion of a floor area is not within the interconnected floor space, the required access to exit from this portion of the floor area shall not lead through the interconnected floor space.

Sentence 3.3.1.9.(8)Corridors

A dead end corridor is permitted in an assembly occupancy where there is a second and separate egress doorway from each room or suite not leading into a dead end corridor.

5. **Applicant's Position**

The Applicant submitted that the proposed walkway need not be enclosed and provided with a 30 minute fire separation. In their view, the open bridge provides sufficiency of compliance with the 1990 Ontario Building Code for the following reasons.

The Applicant argued that the corridors in the southern portions of the second floor of each school wing do not truly represent dead-end conditions due to the fact that an alternate exit is available via the proposed bridge for both schools in the event of an emergency. They noted that each wing has two exit stairs and the bridge would allow occupants to travel to exit stairs on the other side of the building if the ones on their side were blocked.

As the Applicant pointed out, it would be unlikely that a fire emergency on the second floor in one wing of the school would affect both the bridge and the other wing at the same time, thereby making the circumstances that could cause a dead-end situation extremely remote. Similarly, an emergency in the solarium or the general purpose room would simply mean that occupants would use either of the two exit stairs provided in their wing. Further, the 30 minute fire separation proposed for each end of the bridge would allow occupants time to use the exits provided in their wing of the building.

The Applicant also noted that the solarium and the general purpose room will have limited combustible fire loads. As well, these two rooms will be separated from the classroom wings by a 30 minute fire separation.

Essentially, the Applicant contended that the bridge could be considered as an open mezzanine within the solarium and general purpose room since, in their opinion, the proposed bridge satisfies Sentence 3.2.1.1.(3) of the OBC regarding mezzanines. To support this assertion the Applicant noted that the bridge, at 120 m^2, is only 12.5 % of the 960 m^2 room in which it is located, will be used as an open floor area, and will be provided with a 1,070 mm guard on both sides.

It follows, the Applicant argued, that an open mezzanine is not subject to the interconnected floor space requirements found in Sentence 3.2.8.2.(9) of the Code, in particular the 30 minute vertical fire separation where a floor opening is adjacent to a corridor. Specifically, they pointed

out that the proposed bridge complies with Clause 3.2.8.2.(1)(c) which permits an open mezzanine not to terminate at a vertical fire separation where every point on the mezzanine is within 25 metres of a point that can allow an occupant to view 60 % of the room, and is not a Group B occupancy.

The Applicant also discussed Sentence 3.3.1.5.(2). which requires that every mezzanine without a vertical fire separation shall have two egress facilities placed in such a manner that at least one be accessible in certain situations. On this point, the contended that the proposed bridge will have better egress than that required under this provision of the OBC.

The Applicant conceded that a strict interpretation of the Code may lead one to believe a 30 minute fire separation is required for the bridge in question. Based on the reasons described above, however, the Applicant is of the belief that proposed walkway provides sufficiency of compliance with the relevant provisions of the Building Code.

6. **Chief Building Official's Position**

The Respondent submitted that the proposed bridge is part of the corridor system of the school and thus OBC 3.2.8.2.(9) applies, making a 30 fire separation at the walkway edges mandatory.

In the Respondent's view, the two second floor corridors at the school's south end have dead-end conditions. As they note, there are no second and separate egress doorways from each room that does not lead into the corridor, as required under Sentence 3.3.1.9.(8). Further, the requirement found in Clause 3.2.8.2.(9)(f) prohibits an access to exit within an interconnected floor space. Assuming that the bridge is a mezzanine, i.e. considered to be part of the first storey, within the solarium and the general purpose room also did not satisfy the Respondent that a second means of egress could be established. They pointed out that as part of the first storey, the bridge cannot serve as a means of exit for corridors on the second floor, unless the penetration between storeys is by means of an exit conforming to Section 3.4, which under Sentence 3.4.4.1.(1) requires a 1 hour separation.

The Respondent submitted a letter from the Applicant's agent stating that the 30 minute fire separation in question would be built in return for the Respondent considering the generalpurpose room and the solarium as a combined space for determining occupant load. At the time, the Respondent noted that the Applicant agreed to considered these two spaces as not serving as an access to exit from either school. In the Respondent's view, the proposal at hand violates these two agreements.

The Respondent also expressed concerns about the proposed unenclosed walkway because they felt that the heavy timber roof assembly and the combustible flooring of the general purpose room represented enough of a combustible load that occupants travelling across the bridge would be exposed to dangerous levels of smoke.

The Respondent rejected the Applicant's argument that the bridge can be viewed as a mezzanine. While admitting that the bridge may have appeared to have met the open mezzanine requirements, it was their belief that it is the intent of the Code that the interconnected floor space requirements of 3.2.8.2.(9) should apply to this situation. They cited the 1997 version of the OBC, claiming that the new Code has made it clearer that the interconnected floor space standards are applicable in this circumstance.

7. **Commission Ruling**

It is the decision of the Building Code Commission that the unenclosed walkway serving as an alternate access to exit from the second floor school building does not provide sufficiency of compliance with Sentence 3.2.8.2.(9).

8. **Reasons**

i)The walkway is a required access to exit from the second storey to eliminate dead-end corridors.

ii)As a corridor it is required to be separated by a fire separation having a 1/2 hour fire resistance rating from the remainder of the building, as required by Sentence 3.2.8.2.(9).

iii)No alternate measures were included to compensate for the life safety hazard of exiting through an interconnected floor space via an open bridge in an elementary school.

RULING

1. **The Applicant**

   Mr. and Mrs. Terry Dingle, homeowners, have applied for a building permit under the *Building Code Act, 1992* to add a two-storey addition at 47 Walker Avenue, Toronto, Ontario.

2. **Description of Construction**

   The Applicants propose to renovated an existing semi-detached house and add a two storey addition to the rear of the subject building. The building is constructed of combustible construction and has a building area of approximately 106.9 m^2 (1,150 ft^2). The structure is classified as a Group C, residential occupancy.

   As part of this work, the Applicants proposed to add a strip window on the east side of the new addition. (The subject semi-detached dwelling is attached on its west side.) The dimension of the window are 3.5 m by 0.76 m (11 ft, 6 in by 2 ft, 6 in). It has a total area of 2.04 m^2 (22 ft^2). The east exposing face of the proposed addition is .94 metres (3 ft, 1 and 1/4 in) from the adjacent property. The Applicants propose however to set the window itself, or the actual glazed surface, back from the exposing face within the house by 0.37 m (14 and 5/8 in) so that the window

would be 1.32 m (4 ft, 3 and 7/8) from the property line. The window structure would be supported inside the addition by several gables.

3. **Dispute**

The issue at dispute between the Applicant and Respondent is whether the proposed windows, as unprotected openings, with a limiting distance of .94 metres from the adjacent property line, provides sufficiency of compliance with Article 9.10.14.1. of the Ontario Building Code. This provision allows seven percent of an exposing building face to be unprotected openings where the limiting distance is 1.2 metres (3 ft, 11 in). Where the limiting distance is less than 1.2 metres no unprotected openings are allowed.

4. **Provisions of the Ontario Building Code**

Article 9.10.14.1Maximum Percentage of Unprotected Openings

(1) Except as provided in Sentence (2) and in Articles 9.10.14.3. to 0.10.14.11., the maximum percentage of unprotected openings in an exposing building face shall conform toTable 9.10.14.A. or to Subsection 3.2.3., whichever is the least restrictive for the occupancy being considered.

(2) An opening in an exposing building face not more than 130 cm^2 (20 in^2) shall not be considered an unprotected opening.

5. **Applicant's Position**

The Applicant submitted that since the windows are recessed into the exposing face the actual limiting distance, as measured from the unprotected openings to the property line, is more than 1.2 metres (3 ft, 11 in). At this distance, they argued, the OBC allows seven percent of the exposing building face to be unprotected openings. The Applicants calculated that seven percent of the subject exposing face would be 8.71 m^2 (93.7 ft^2). They noted that this is well in excess of the 2.04 m^2 proposed for the strip windows.

The Applicants also argued that the proposed window, in fact, improves the original situation of unprotected openings in this exposure because they have decided to permanently close off an existing basement window located only 0.9 metres (3 ft, 1 in) from the lot line.

City of Toronto By-Law 438-86 which allows a window within 1.2 metres (3 ft, 11 in) of an adjacent structure in a semi-detached zone was raised by the Applicant. They contended that the Respondent was not adhering to the standards in their own by-laws with respect to the window at issue.

Lastly, the Applicants felt that the inclusion of the window is an important aspect of the renovation because it brings light deep into the house and thus improves the liveability of the addition.

For these reasons, the Applicant argued that the recessed window at issue still meets the intent of the Building Code.

6. **Chief Building Official's Position**

The Respondent submitted that the proposed window does not provide sufficiency of compliance with Article 9.10.14.1. They referred to the definitions of "Exposing Building Face" and "Limiting Distance" in the OBC to make their case. The Respondent noted that the OBC definition for exposing face clearly refers to the exterior wall of a building and not the recessed window strip as proposed and designed by the Applicants. They further noted that the OBC, as it defines limiting distance, is a measurement from the exposing face to a set point. They emphasized that while the point to which the limiting distance is measured can vary from either the property line, the centre of a street, or to an imaginary line between two buildings, etc., the exposing face is a fixed point. The Code does not allow limiting distance calculations to made on variations in the exposing face for recessed windows.

As a result, the Respondent pointed out that the subject exposing face has a limiting distance of less than 1.2 metres (3 ft, 11 in) and thus according to Table 9.10.14.A. is allowed zero percent unprotected openings. As the requirements in the OBC are minimum standards, the Respondent stated that they cannot accept the proposed variation.

7. **Commission Ruling**

It is the decision of the Building Code Commission that the proposed windows demonstrate sufficiency of compliance with the requirements of the Building Code provided that:

a)Wired glass in fixed steel frames is installed in the proposed windows with the unprotected opening limited to no more than 1.12 m^2 (12 ft^2).

8. **Reasons**

i)A portion of the window opening will be protected with wired glass in steel frames.

ii)Windows were removed from the existing building that measured approximately 1.12 m^2 (12 ft^2).

iii)The new window is inset from the exterior wall and is installed at a distance of 1.32 m (4 ft, 3 and 7/8 in) from the property line.

iv)Centrally monitored fire alarms and two portable fire extinguishers have been installed in the home.

Dated at Toronto this 24th day in the month of April in the year 1998 for application number 1998-19.

RULING

1. **The Applicant**

   Mr. Paul Malin, Senior Fire Protection Engineer, Morrison Hershfield Ltd., has been issued an order under the *Building Code Act, 1992* to raise the subject ceiling to 2,100 mm (6 ft, 11 in) in conformance with Sentence 3.4.3.7.(1) of the Ontario Building Code at 1050 Broadview Avenue, Toronto (East York), Ontario.

2. **Description of Construction**

   The Applicant recently renovated a fifteen storey (plus parking garage) apartment building with a building area of 635 m^2 (6,840 ft^2). The building is constructed of noncombustible construction. It is equipped with a fire alarm system, a standpipe and hose system and an automatic sprinkler system in the garage level only. The building is classified as a Group C, residential occupancy.

The renovation included installing a new drop ceiling in certain portions of the building. The disputed areas where the ceiling heights are less than 2,100 mm (6 ft, 11 in) are the main entrance and the corridor leading to the elevators, the management office and the annunciator panel. In these locations the newly installed drop ceiling averages 2,088 mm (6 ft, 10 1/2 in) in height. In some places the ceiling is as low as 2,075 mm (6 ft, 10 in). As a result, an order to comply was issued on December 5, 1997 to raise the subject ceilings.

3. **Dispute**

The issue at dispute between the Applicant and Respondent is whether the subject ceilings, at a height averaging 2,088 mm (6 ft, 10 1/2 in), provides sufficiency of compliance with Sentence 3.4.3.7.(1) of the Ontario Building Code. This provision requires a headroom clearance of 2,100 mm (6 ft, 11 in). At issue is whether the Applicant will be required to raise the ceiling height in the disputed area as per the order to comply.

4. **Provisions of the Ontario Building Code**

Sentence 3.4.3.7.(1)Headroom Clearance

(1) Except as provided in Sentences (2) to (4), every exit shall have a headroom clearance of not less than 2,100 mm (6 ft, 11 in).

5. **Applicant's Position**

The Applicant submitted that the recently installed drop ceiling at a height slightly lower than that required in Sentence 3.4.3.7.(1) provides sufficiency of compliance. They argued that the variation was only minor and could be viewed as an acceptable construction tolerance.

The Applicant stated that the construction in dispute, as a basic renovation, where no new occupancy nor increase in occupant load is proposed, can be subject to Part 11 of the OBC. In particular, they pointed to Sentence 11.3.2.1.(1) which allows the renovation to match the existing conditions. As well, they noted that compliance alternative C45 (Table 11.2.3.C/Residential) allows existing headroom clearances of not less than 1,980 mm (6 ft 6 in).

Regarding Article 3.4.3.7., the Applicant indicated that the four sentences found within this Article allow for different ceiling heights for different situations such as headroom clearances in exits, on stairs, in doorways and below door closers. They argued that this represents a clear indication that different clearances are allowed in certain traffic areas. As a result, this slight

variation is less significant. Further, the Applicant argued that the OBC headroom clearance standards are based on average population heights. In their view, this means that the standards are somewhat arbitrary in nature and not a precise science.

For these reasons, the Applicant argued that the slightly lower ceiling at issue still meets the intent of the Building Code.

6. **Chief Building Official's Position**

The Respondent submitted that the as built ceiling height does not meet Sentence 3.4.3.7.(1) of the OBC. They noted that the deviation from the required standard was a much as 24 mm (1 in) in some places. They argued that since the construction in dispute is new, it does not fall within the scope of Part 11. The 2,100 mm (6 ft, 11 in) standard found in Sentence 3.4.3.7.(1) applies and, as the Respondent pointed out, the Code does not provide tolerances. As the requirements in the OBC are minimum stand ards, the Respondent stated that they cannot accept this variation.

7. **Commission Ruling**

It is the decision of the Building Code Commission that the construction provides sufficiency of compliance with the requirements of the Building Code.

8. **Reasons**

i)Removing the stairs improves the access to exit through the lobby.

ii)There has been no increase in hazard as occupancy classification and occupant load have not changed.

iii)Evidence submitted indicates the new ceiling has been installed at essentially the same level as the existing ceiling.

iv)Evidence submitted indicates that the new floor level at the elevators which has been extended through to the front doors, is at essentially the same level as the existing floor level at the elevators.

v)Raising the ceiling level is impracticable because of existing services within the ceiling space.

Dated at Toronto this 9th day in the month of April in the year 1998 for application number 1998-15.

BCC Ruling No. 98-16-621

BUILDING CODE COMMISSION DECISION ON B.C.C. #98-16-621

IN THE MATTER OF Subsection 24 (1) of the *Building Code Act, 1992*.

AND IN THE MATTER OF Article 9.4.1.1. of Regulation 61, as amended by O. Reg. 400/91, 158/93, 160/93, 383/94, 20/95 and 395/96 (the "Ontario Building Code").

AND IN THE MATTER OF an application by Mr. Richard Epple, President/Owner, 657602 Ontario Incorporated, 16 Stubbs Court, Tillsonburg, Ontario for the resolution of various disputes with Mr. Douglas Robertson, Chief Building Official, Town of Tillsonburg, Ontario to determine, among other things, whether the subject building is required to meet the structural requirements under Article 9.4.1.1. of the Ontario Building Code at 67 Simcoe Street, Tillsonburg, Ontario.

The Respondent

RULING

1. **The Applicant**

   Mr. Richard Epple, President/Owner, 657602 Ontario Incorporated, has applied for a building permit under the *Building Code Act, 1992* to construct a one storey, multi-unit mercantile/business plaza at 67 Simcoe Street, Tillsonburg, Ontario.

2. **Description of Construction**

   The Applicant proposes to construct a one storey mercantile plaza with a building area of 230 m^2 (2,475 ft^2). The building is constructed of noncombustible construction with a block exterior wall and an open web steel joist roof supported by intermediate steel columns. It is equipped with a fire alarm system. The structure is classified as a Group D - business occupancy.

   It is the intention of the Applicant to divide the building into two halves, with one half used as a single unit by a spa and hot tub retail store and the other half used by the Applicant himself. In the Applicant's half, he proposes to use one third of the space to create an office unit for his own business and the other two thirds as a separate unit for a building supply shop also operated by 657602 Ontario Incorporated.

The site on which the building is proposed was previously occupied by a motel. The soil conditions, especially regarding imported topsoil, are unknown.

In terms of spatial separations, the proposed building is considered to face two streets. The distances to the property lines for the remaining two sides of the building are 1.2 m (4 ft) on the south side and 3 m (10 ft 6 in) on the west side.

The Applicant proposes to install two washrooms, one in either half, located at the rear of the building. Wastewater is to be discharged to the existing sanitary sewer located to the east under Pine Street. Fresh water will be drawn from the main at the front end of the lot facing Simcoe Street. Stormwater will be collected through a drain in the centre of the building and discharged to a catch basin under the parking area at the front of the building. Heating and ventilation will be provided by two units located on the roof of the building.

3. **Dispute**

There are various disputes concerning the subject building between the Applicant and Respondent. Initially the Applicant submitted a list of ten disputed areas, however, as some of the issues were beyond the mandate of the Building Code Commission he subsequently withdrew five of the disputed areas. The five remaining items are listed below.

1)Whether the subject building is required to meet the structural requirements under Article 9.4.1.1. of the Ontario Building Code.

2)Whether the soils have been investigated by a qualified person as per Article 4.2.2.3. of the OBC to ensure that their bearing capacity is adequate.

3)Whether the spatial separations conform to Article 9.10.14.1. of the OBC.

4)Whether the plumbing systems for the washrooms, accessibility for barrier free design, roof drainage and separation between units complies with the respective standards in the OBC.

5)Whether all other requirements of the OBC had been met. The Applicant sought clarification as to the precise meaning of this condition applied by the municipality.

4. **Provisions of the Ontario Building Code**

Article 9.4.1.1. Structural Design

(1) Except as provided in Sentence (2) and Sentence 9.23.4.1.(2), Subsections 9.4.2. to 9.4.4. and Subsection 9.40.3., structural members and their connections shall be designed in conformance with Part 4.

(2) Where structural members and their connections conform to the requirements listed elsewhere in this Part, it shall be deemed that the structural design requirements have been met.

Article 4.2.2.3.Reviews

(1) A review shall be carried out by the designer or by another suitably qualified person to ensure that the subsurface conditions are consistent with the design and that construction is carried out in accordance with the design and good engineering practice.

(2) The review required in Sentence (1) shall be carried out

(a) on a continuous basis

(1)During the construction of all deep foundation units with all pertinent information recorded for each unit, and
(ii)During the installation and removal of retaining structures and related backfilling operations, and

(b)as required, unless otherwise directed by the authority having jurisdiction,

(I)In the construction of all shallow foundation units, and
(ii)In excavating, de-watering and other related works.

Article 9.10.14.1. Maximum Percentage of Unprotected Openings

(1) Except as provided in Sentence (2) and in Articles 9.10.14.3. to 9.10.14.11., the maximum percentage of unprotected openings in an exposing building face shall conform to Table 9.10.14.A., or to Subsection 3.2.3., whichever is the least restrictive for the occupancy being considered.

(2) An opening in an exposing building face not more than 130 cm (20 in) shall not be considered an unprotected opening.

5. **Applicant's Position**

The Applicant submitted the following presentations regarding the five issues.

1) The Applicant argued that drawings stamped by an engineer analysing the complete structural design were not necessary for the subject building. He noted, however, that an engineering firm was retained and he submitted a letter from them covering all disputed issues and that stamped drawings were submitted for the structural steel. Regarding other aspects of the structural design, the Applicant noted that his engineer, upon review of the drawings prepared by the Applicant and the structural steel fabricator, stated they were adequate for the construction of the proposed building with two minor additions. (The items added were a pier and footing under the central column and that all pilasters and block work supporting structural steel is to be reinforced with 15 m rebar and filled with concrete.) The Applicant further noted that the engineer would undertake to inspect the structural construction of the building to ensure it meets OBC standards.

2) Regarding the soil adequacy, the Applicant again referred to the engineer's letter. It stated that the building as designed requires soils with a bearing capacity of 2,000 psi. The engineer believes that the soils at the subject site can easily provide this capacity. The Applicant indicated that the engineer would inspect the excavation before the pouring of footings. The Applicant reiterated his engineer's view that confirmation of soil capacity is not required before a building permit can be issued.

3) The Applicant asserted that the spatial separation of the proposed building is adequate. Since the north and east exposures face streets, it is only the south and west exposures where the unprotected openings must be calculated with respect to the limiting distance. The engineering analysis conducted for the Applicant states the west exposure, at 1.2 m (4 ft), is allowed 7% of the exposing wall to be unprotected openings, or up to 14% if both side yards are counted. The Applicant indicated that since he owns the adjacent property to the west he is planning to build a lane between the proposed building and the existing one to the west. This would mean that the unprotected openings would meet OBC standards. At the hearing, the Applicant also stated that he would consider registering on title of the two adjacent properties he owns (the subject one and the one to the west) in order to satisfy the limitingdistance requirements. For the south wall at the rear of the building, the Applicant claimed that the 3 m (10 ft 6 in) distance allows 18% unprotected openings. This will more than suffice for the proposed openings.

4) The Applicant described the plumbing, drainage, heating and ventilation systems. He indicated that they all meet Code standards as proposed.

5) The Applicant reiterated his request for clarification as to what the Tillsonburg Building Department meant with their request that all other OBC requirements be met. In the Applicant's view, his project had been unfairly scrutinized by his local building department with unnecessary requirements being asked of him. Lastly, the Applicant stated that his engineer would review the entire project to ensure Code compliance.

For these reasons, the Applicant argued that his building as designed should be issued a building permit.

6. **Chief Building Official's Position**

The Respondent addressed each one of the issues raised. His response was as follows.

1) The Respondent argued that according to Article 9.4.1.1. structural members and their connections must conform to the requirements of Part 4 of the OBC or the structural requirements found in Part 9, in which case the structural design shall be deemed to have conformed with the OBC's structural requirements. Since the design does not conform to the structural standards found in Part 9, in the Respondent's opinion, based on Article 9.4.1.1., the building must be designed in accordance with Part 4, meaning that the plans submitted must be certified by an engineer or a qualified person. As an example of how the proposed building does not meet the structural standards in Part 9, the Respondent pointed to Sentence 9.15.3.3.(2) which states that where the supported joists exceed 4.9 m (16 ft 1 in), as in the case of the subject building, the footings shall be designed according to Section 4.2. The Respondent noted that the structural steel drawings were not submitted to him until last week. He also indicated that there was a discrepancy between the building size shown on the site plan and the building drawings. He attributed this to the Applicant using engineering drawings from another building.

2) The issue of soil verification was a misunderstanding, the Respondent believed. In his correspondence with the Applicant the Respondent meant to communicate that soil verification may be required if necessary, not that it must be required prior to the issuance of a building permit. As the Respondent explained, the motel that previously occupied the site may have used imported fill during its construction. This was the basis of his soil-related concerns.

3) Concerning spatial separations, the Respondent indicated at the time of the review when the dispute arose that no elevation drawings had been submitted to the municipality. There had been no discussion at that point either regarding the west exposure in terms of registering on title the limiting distances of the buildings. The Respondent indicated that he would accept the

registrations on title. He rejected, however, the engineer's claim that if a lane were constructed between the adjacent existing building own by the Applicant and the one currently proposed that OBC compliance would result. As the Respondent argued, Subsection 9.10.14. dealing with spatial separation measures the limiting distance to the lot line, not the adjacent building. Regarding the south exposure, he noted that the OBC allowed 10 % unprotected openings, and judging from the rough sketches provided by the Applicant, the proposed openings appeared to exceed the allowable limit by one or two per cent.

4) The Respondent also indicated that no drawings were submitted detailing the plumbing, drainage and heating and ventilation systems. Without such plans the Respondent indicated that they could not properly review the plumbing system serving the two proposed washrooms. Nor could they review the drainage system for the roof stormwater. The Respondent indicated that their concern was that the pipes proposed for transporting stormwater to the catch basin pass through air plenums, meaning that they are required to meet the appropriate fire stopping standards in the OBC. The Respondent was also seeking details on how the Applicant proposes to provide adequate fire separations between his office space and his adjacent retail occupancy.

5) The respondent explained that the final issue, requiring the Applicant to comply with all other OBC standards, was a standard message meant to communicate to the Applicant that when the completed drawings or other requirements were submitted there may still be clarifications needed from the Applicant after a review. As the Respondent noted, since certain essential drawings and other information had not yet submitted for this project they felt it was especially prudent to include this message on correspondence with the Applicant.

7. **Commission Ruling**

It is the decision of the Building Code Commission that the proposed construction demonstrates sufficiency of compliance provided:

i)At the discretion of the municipality, a soil investigation will be performed prior to pouring the footing.

ii)Spatial separations comply with the requirements for the Code, and are registered on title of both properties owned by the applicant where limiting distances to the lot line are exceeded.

iii)Additional plumbing, heating and ventilation details are provided as required by the municipality to ensure code compliance.

8. **Reasons**

Additional information was received at the hearing which addressed a number of issues raised at the time of application and included drawings acceptable to the Chief Building Official.Dated at Toronto this 9th day in the month of April in the year 1998 for application number 1998-02.

RULING

1. **The Applicant**

   Mr. Cyril Mayo, Project Coordinator, The Board of Education for the City of London and Mr. Clive Matthews, Manager of Building Services, City of London have applied for a building permit under the *Building Code Act, 1992* to renovate an existing school by adding a pool facility and adding a new school facility to the entire structure at the South London Community and Leisure Centre and the White Oaks/Bradley Avenue Public School, 565 Bradley Ave., London, Ontario.

2. **Description of Construction**

The Applicants propose to renovate an existing, two storey school building by adding a two storey addition containing a school and a pool. The pool is also intended to be used as a community pool. The pool addition will add 1,438 m^2 to the building respectively. Together both portions of the addition will add 6,702 m^2 of new building area to the structure. Including the existing building, the proposed structure will have a total building area of 9,412 m^2.The protructure is classified as a Group A - Division 2 building containing two occupancies, a non-residential school and a community centre which includes a pool.

Between the two occupancies, the Applicants are proposing to have free circulation during school hours. After school hours, however, the Applicants wish to separate the school and pool occupancies through the installation of electro-magnetic locking devices on one leaf only of a pair of double egress doors on both the ground and second floors. The subject double egress doors, proposed for the central east-west corridors on both floors, are considered to be in an access to exit.

3. **Dispute**

The issue at dispute between the Applicant and Respondent is whether the proposed separation of the pool and school occupancies by an electromagnetic locking device provides sufficiency of compliance with Sentence 3.3.1.12.(3) of the Ontario Building Code. This provision specifically prohibits a door in an access to exit in a school from being equipped with an electromagnetic locking device.

4. **Provisions of the Ontario Building Code**

Sentence 3.3.1.12.(3)Doors

(3) Except for a door in an elementary or secondary school or a door leading directly from a Group F, Division 1 occupancy, a door in an access to exit is permitted to be equipped with an electromagnetic locking device conforming to Sentence 3.4.6.15.(4).

5. **Applicant's Position**

The Applicants submitted that the subject double egress doors are neither exit doors, nor do they provide access to exit. They contended that the proposed doors could be replaced by a solid wall. They argued, in other words, that the doors should be considered as convenience doors, providing better internal circulation in the building only. To prove this point, the Applicants

pointed to the fact that there are no exit signs, nor way-finding signs to indicate that the subject doors are in fact exit related doors. Further, they argued that unlike exit doors, these doors will remain open most of the time.

The Applicants insisted that the double egress doors are for security purposes, hence the electromagnetic locking device on one door only of the two pairs. The intention of this design is to keep users of the community centre out of the school area after hours.

For these reasons, the Applicants submitted that Sentence 3.3.1.12.(3) does not apply and therefore the proposed installation of the electromagnetic locking device on the subject doors should be allowed.

6. **Chief Building Official's Position**

The Respondent agreed that the doors in dispute, although technically considered access to exit doors, are intended mostly to allow students access to the pool area without going outside. They submitted that their opposition to the installation of electromagnetic locking devices is due mostly to the fact that Sentence 3.3.1.12.(3) of the OBC clearly does not permit such devices on access to exit doors. As a result, they noted that they do not have the authority to deviate from these requirements of the Code.

7. **Commission Ruling**

It is the decision of the Building Code Commission that the proposed installation of an electromagnetic locking device on one leaf of two pairs of the double egress doors provides sufficiency of compliance with the Building Code provided that:

i)Magnetic locks are installed only on access to exit doors from the pool into the school.

ii)A manual over-ride for magnetic locks is provided at the control desk for the pool.

iii)The magnetic locks are connected to, and released by activation of, the fire alarm system.

8. **Reasons**

i)The magnetic locks will only be activated by the school security systems when the school is vacant.

ii)The facility has a centrally monitored fire alarm system.

iii)The facility is protected by an automatic sprinkler system with alarms connected to a central station monitoring system.Dated at Toronto this 25th day in the month of March in the year 1998 for application number 1998-13.

RULING

1. **The Applicant**

   Mr. Milo Janecek, President, Paramount Construction Ltd., was issued an order to comply under the *Building Code Act, 1992* to install a thermal barrier in the roof assembly at the precision tool sales and warehouse building known as the Sowa Tool plant, Kitchener, Ontario.

2. **Description of Construction**

   The Applicant recently added a 835.7 m^2, one storey addition to an existing precision tool sales and warehouse building. Including the addition, the expanded structure has a total building area of 2,154.1m^2 and is considered to be one storey in building height. The older portion of the building contains a small mezzanine that comprises only 0.036 % of the ground floor area. The existing building is constructed of noncombustible construction, with the exception of a 50 mm (2 in) thick wood deck in the roof assembly of the oldest portion of the existing building.

The recently constructed addition is also built of noncombustible construction. It contains a 25 mm (3 in) thick combustible foam plastic insulation (Roofmate) which is not protected by a thermal barrier between the 40 mm (1.5 in) steel roof deck and the insulation. The roof assembly also contains a vapour barrier above the deck but below the Roofmate insulation, as well as a 25 mm (1 in) insulation board above the Roofmate, and topped off with a 4-ply built-up roof to match the existing. The roof assembly of the addition is supported by steel joists.

The expanded building is equipped with a single-stage fire alarm system that monitors both alarm and supervisory signals and is connected to Sowa Tool's burglar alarm system. The building does not have a sprinkler system nor a standpipe and hose system. It has fire route access on the north, south and west faces of the building. A fire hydrant is located approximately 45 m (150 ft) from the west side of the building. Also, exit lights with emergency power provide lighting for the principal exit routes.

The building is classified as a Group F - Division 3, low hazard industrial occupancy.

3. **Dispute**

The issue at dispute between the Applicant and Respondent is whether the addition, as constructed, without a thermal barrier in the roof assembly, but including other measures, provides sufficiency of compliance with Clause 3.1.14.2.(2)(a) of the Ontario Building Code. Sentence 3.1.14.2.(2) allows a building with a metal roof deck assembly containing a combustible material to waive the conditions of acceptance of CAN/ULC-S126-M provided that certain conditions are met. One of these conditions, found in Clause (a) of Sentence 3.1.14.2.(2), is that the roof assembly contain thermal barrier. The new roof assembly in thesubject addition contains Roofmate, a combustible foam plastic insulation, however, no thermal barrier was installed. The Applicants are proposing other compensating measures, namely greater fire department access routes.

4. **Provisions of the Ontario Building Code**

Clause 3.1.14.2.(2)(a)Metal Roof Deck Assemblies

(2) The requirements of Sentence (1) are waived provided

(a)the combustible material above the roof deck is protected by a thermal barrier conforming to Clause 3.1.5.11.(2)(e) that is located

(i)on its underside, or
(ii)beneath the roof deck,

5. **Applicant's Position**

The Applicant submitted that the building should be considered as a structure conforming to Article 3.2.2.56. of the OBC, instead of Article 3.2.2.57. as has previously been the case. This alternate approach would allow the recently constructed roof assembly to remain, since Article 3.2.2.56. permits one storey, division 3, industrial buildings to be constructed of combustible construction. This would mean that the roof assembly would not have to comply with Article 3.1.14.2. regarding thermal barriers.

The Applicant recognized that in order to use this alternate approach under Article 3.2.2.56. the building must qualify under the conditions of this provision. Considering that the building is one storey, unsprinklered and is 2,154.2 m^2 in building area this means that the building must face three streets. Currently, the building is considered to face two streets and in order to be considered as facing three streets the structure must have 75 % of the perimeter within 15 m of a fire access route. The Applicant noted that the building perimeter, including the addition, is approximately 236.2 m (775 ft) with 159.4 m (523 ft), or 67.5 %, of it within 15 m of a fire department access route. They contended that this extent of fire access routes does comply with Article 3.2.2.56. if an interpolative method is used, i.e. using the known figures in Table 3.2.2.W. to estimate another figure somewhere between those numbers. In this case, the figures relate to building area with respect to the number of streets the building faces.

Specifically, the Applicants argued that if, under Article 3.2.2.56., a building facing 2 streets, i.e. having 50 % of the perimeter within 15 m of a fire route, is allowed to be 2,000 m^2 in building area and if a building facing 3 streets, or having a fire route along 75 % of its perimeter is permitted to be 2,400 m^2, then a structure with a building area of 2,154.2 m^2 should only be required to have a fire route on 59.6 % of the perimeter. In the Applicant's view, the interpolative method offers a sliding scale of perimeter required as fire route depending on building area. On this basis the Sowa Tool warehouse, with 67.5 % of its perimeter as fire route, meets and exceeds the condition of Article 3.2.2.56.

The Applicant also noted that they have also provided other measures in excess of OBC requirements that are intended to improve the safety of the facility. For example, the single-stage, single zone fire alarm system is monitored by an agency with a direct alarm connection to the local fire department. This system will be upgraded in a few months to a ULC listed central

monitoring station. The facility also has an audible carbon monoxide alarm system. Finally, the building is equipped with exit signs even though the occupant load is only 40. The Code requires such signage when the occupant load reaches 150 people.

6. **Chief Building Official's Position**

The Respondent submitted that the thermal barrier required in the roof assembly was not installed as indicated on the permit drawing that were submitted and reviewed. As a result, they issued an order to comply on November 26, 1997. Further, the Respondent rejected the alternate approach of considering the building under Article 3.2.2.56. since the OBC does not permit the interpolation of the percentage of the building perimeter to determine the number of streets for fighting purposes. In their opinion , the structure remains subject to the requirements of Article 3.2.2.57. The Respondent also noted that to date the Applicant has refused to install a sprinkler system, which they feel would compensate for the lack of a thermal barrier.

7. **Commission Ruling**

It is the decision of the Building Code Commission that the roof construction of the one storey addition shows sufficiency of compliance with the Ontario Building Code provided that;

fire deparment access is maintained on the north side of the building as well as on the west and south sides.

8. **Reasons**

a)The owner is allowing only parallel parking adjacent to the building on the north side to maintain fire department access on that side.

b)Additional fire safety measures have been provided, viz;

i)the building is equipped with a single stage fire alarm system that will transmit a signal to the fire department through an off site monitoring station that will be ULC listed as a central station.

ii)exit signs are provided in the building.

For the Respondent

RULING

1. **The Applicant**

   Mr. Cos Orsini, Director, Orsini Bros. Inc., has applied for a building permit under the *Building Code Act, 1992* to renovate an existing hotel structure by adding a seventh floor presidential suite at the Niagara Falls Ramada Suites Hotel & Conference Centre, Niagara Falls, Ontario.

2. **Description of Construction**

   The Applicant proposes to construct an addition to an existing six storey hotel. The addition will add a seventh level comprising 1,268 ft^2 at the south-east corner of the top of the existing structure. This additional level is intended to be used as a presidential suite catering to high-end clientele. The proposed presidential suite would be accessed by a new flight of stairs to be built off the existing elevator lobby of the sixth floor. The elevators would not be extended to the presidential suite.

The proposed seventh level would be constructed of noncombustible construction, with the floor and load bearing walls of the proposed presidential suite having a 2 hour fire-resistance rating. The roof of the presidential suite is to have a fire-resistance rating of 1 hour, using the ULC #1501 design.

The existing structure has a building area of 68,256 ft^2 and is constructed of noncombustible construction, with floor and load-bearing wall assemblies and exit stairwells having a fire-resistance rating of 2 hours. The doors and frames have a 1.5 hour rating. It is equipped with a standpipe and hose system and a fire alarm system. It is not provided with a sprinkler system. The building is classified as a Group C - residential (hotel) occupancy.

3. **Dispute**

The issue at dispute between the Applicant and Respondent is whether the proposed addition can be considered a mezzanine under Sentence 3.2.1.1.(4) of the Ontario Building Code and thus be subject to the exiting requirements for a mezzanine, specifically OBC Sentence 3.4.2.1.(1). By adding a seventh level, which if defined not as a mezzanine but as a storey having a floor area, the proposed presidential suite would then be required to provide a minimum of two exits. This could only be accomplished by creating an 80 ft long exit path over the top of the existing hotel roof to the north stair, which would have to be raised one storey to the seventh level. Considered as a mezzanine, however, only one exit would be required from the presidential suite.

4. **Provisions of the Ontario Building Code**

Sentence 3.2.1.1.Exceptions to Building Height in Storeys

(4) Except as provided in Sentence (5), a mezzanine shall not be required to be considered as a storey in calculating building height and need not conform to Sentence (3) where the aggregate area of the mezzanine floor does not exceed 10 percent of the area of

(a)the suite in which it is located, where there is more than one suite in the storey, or

(b)the storey in which it is located, in all other cases.

5. **Applicant's Position**

The Applicant submitted that the proposed presidential suite addition should be considered as a mezzanine to the sixth floor. In their opinion, providing a second exit across the top of the

existing sixth floor roof would not be practical. Individuals exiting the presidential suite would have to travel over 80 ft across a sixth storey high roof. This situation itself would be dangerous and would require the hotel to construct either a 3 ft, 6 in guard around the perimeter of the existing roof, a length of 244 ft. Or, in order to avoid the problems of keeping such a path clear in the winter, an 80 ft long enclosed walkway would be necessary.

The Applicant argued that the seventh level addition could be viewed as a mezzanine since the presidential suite at 1267.59 ft^2 comprises only 14.82 % of the 8,548.27 ft^2 of the sixth floor area below. As they noted, this is only 4.82 % in excess of the 10 % allowed for a floor area to be considered a mezzanine.

Regarding the exiting from the presidential suite, the Applicant asserted that the proposed addition would meet the exiting requirements for a mezzanine under Article 3.4.2.2. Further, as a Group C occupancy with only one exit, the proposed floor area at 1,267.59 ft^2 and the proposed travel distance at 52 ft comply with the standards specified in Table 3.4.2.A which allow a maximum floor area of 1,350 ft^2 and a maximum travel distance of 82 ft respectively.

The Applicants also argued that the presidential suite is safe because the stair leading to the access to exit is in clear view for the occupants of the room and is marked with an exit sign. The suite will not be used as an assembly area, therefore the occupant load will be low. As well, this usage, or lack thereof, was made clear by the city when it dealt with the associated minor variance application to increase parking at the hotel due to the new casino operation earlier this year.

The Applicants pointed out that although they are requesting that the presidential suite be considered a mezzanine, they are not seeking relaxations from other Code standards regardingseven storey buildings as regulated under Article 3.2.2.38. They recognize that, as a result of the presidential suite addition, the hotel can no longer be classified under Article 3.2.2.37. The Applicants note, however, that the subject building does in fact conform to the higher standards under Article 3.2.2.38. This is true of the existing building and will also hold for the proposed addition. Nonetheless, the Applicants indicated that because the grade to floor level height of the presidential suite (considering it as a mezzanine) is approximately 55 ft, 5 in which is less than the 59 ft, 1 in criteria for high-rise buildings therefore the additional requirements of Subsection 3.2.6. do not apply. The same also applies for Sentence 3.2.8.4.(1) and Articles 3.2.8.10. and 3.2.9.3.

6. **Chief Building Official's Position**

The Respondent submitted that the proposed presidential suite addition cannot be considered as a mezzanine because it does not conform to the definition of mezzanine. The proposed suite is not an intermediate level between the floor and ceiling of the sixth floor. They indicated that the new floor area protrudes through the existing roof.

The Respondent argued that the Applicant was requesting too many exemptions. For example, the proposed exiting clearly does not meet the Code requirements for a floor area hence the Applicant's mezzanine proposal. However, the presidential suite does not meet the definition nor size allowed to be a mezzanine, thus the Applicant has requested further exemptions from the mezzanine provisions. Finally, they note that the Applicant is also seeking a relaxation of the standards for fire separating exits from the adjacent floor area.

For these reasons, the Respondent felt that the proposal sought variances that went beyond their authority.

7. **Commission Ruling**

It is the decision of the Building Code Commission that the addition of a presidential suite does not provide sufficiency of compliance with Sentences 3.2.1.1.(4) and Article 3.4.2.2. of the Building Code.

8. **Reasons**

i)The presidential suite is considered a storey and not a mezzanine as per Article 1.1.3.2. and Clause 3.2.1.1.(4)(a) of the Building Code.

ii)As a partial seventh floor it is required to have not less than two exits as per Sentence 3.4.2.1.(1) of the Building Code.

iii)It is the opinion of the BCC that the proposed alternative life safety features wereconsidered insufficient to provide sufficiency of compliance.

Dated at Toronto this 12th day in the month of March in the year 1998 for application number 1998-04.

The Respondent

RULING

1. **The Applicant**

   Mr. Thomas Phillips, Owner, Part Lot 18, Concession 1, has been issued an order to comply under the *Building Code Act, 1992* to bring a concrete sewage tank, a 50 mm (2 in) drainpipe, an antique toilet, in conformity with the appropriate provisions of the Ontario Water Resources Act, and to allow a municipal inspection prior to further use of this water supply system for the subject farm building at Part Lot 18, Concession 1, Carden Township, Ontario.

2. **Description of Construction**

   The Applicant property contains several buildings, including a two storey, 40 by 80 ft Quonset hut structure that has a building area of 3,200 ft^2. This building is divided into two portions, with the front half containing a 1,280 ft^2 second storey. The lower floor contains laundry, kitchen and washroom facilities. The upper level is used as an open storage area. The rear portion of the Quonset hut is used as a garage. The structure is constructed of combustible construction on the interior with a noncombustible exterior shell. It is classified as a Farm Building under the OBC.

There are numerous areas of the as built construction in dispute. The first deals with the sewage tank which is located approximately 4 feet outside of the building and within several feet of the septic system. This system consists of a raised septic tank, as well as a septic bed, and thus relies upon the sewage tank to function. The sewage tank is presently vented through the main stack of the building, which is located 3 feet inside the structure.

Issue two is the slope of the drainage pipe that runs from the plumbing fixtures in the Quonset hut 34 feet under the floor to the sewage tank on the other side of the structure. The pipe only has a fall of 2 3/8 in. And is supported on wooden cross braces beneath the floor.

The third issue is the lack of certification markings on the installed old-style water closet.

The fourth issue was the lack of a municipal inspection prior to the usage of the plumbing system in the Quonset hut.

3. **Dispute**

The issues at dispute between the Applicant and Respondent is whether the as built and installed venting of the sewage tank, slope of the drainage pipe, old-style toilet without certification labels, and usage of the plumbing system in the Quonset hut at the subject property comply with provisions 5.6.5., 4.8.1.(1), 2.1.5.(2) and 1.8.1.(2) of the Ontario WaterResources Act. Unless the Applicant is able to demonstrate compliance with the OWRA provisions, these aspects of the building must be brought into compliance.

The first three issues relate to technical provisions of the OWRA that were incorporated into the OBC in 1993. The last issue, however, is of an administrative and enforcement nature and thus is not covered by the mandate of the Building Code Commission.

4. **Provisions of the Ontario Building Code**

Article 5.6.5. of Regulation 815 states

Where the diameter of an inlet pipe to a sewage tank is,

(a)five inches or larger, the diameter of the vent pipe from the tank shall be at least four inches; and

(b)less than five inches, the diameter of the vent pipe from the tank shall be the greater of,

i)1 1/4 inches, or

ii)one trade size smaller than the inlet pipe.

Sentence 4.8.1.(1) Every fixture drain and every drainage pipe of three inch size or less shall have a minimum grade of 1/4 in. per foot in the direction of flow.

Sentence 2.1.5.(2) The lack of certification markings on a product or plumbing component shall be regarded as evidence that no certification exits.

Sentence 1.8.1.(2) No plumbing that has been constructed, repaired, renewed or altered shall be put into use until it is inspected and found to be in compliance with this Code.

5. **Applicant's Position**

Regarding the first issue the Applicant submitted that since the sewage tank is not in or under his Quonset hut building then Article 5.6.5. of the OWRA does not apply since that Article regulates sewage tanks that are located in or under any building. The Applicant added that this issue is still not covered by the current OBC.

On the issue of the slope of the drainage pipe, the Applicant referenced Sentence 4.8.1.(3) of the OWRA where it allows a slope lesser than 1/4 inch per foot if the lesser grade can be demonstrated to provide a gravity flow rate of at least two feet per second. The Applicantthen produced a calculation known as the manning formula that demonstrated that the subject drainage pipe would produce an adequate flow rate. While he admitted that the as built pipe, with its lesser slope, would not have the same scouring effect as a 1/4 over one foot grade, the subject pipe has functioned effectively for over six years. Anticipating that problems may occur as a result of the too gradual slope, the Applicant installed a cleanout to facilitate the amelioration of any problems if they were to occur.

The Applicant submitted on the issue of the water closet that it was manufactured by "Standard". Unfortunately, since the toilet is old his search to identify the serial number with American Standard was not successful. However, the Applicant added that the water closet has worked without problems for over six years. Lastly, he made known his willingness to temporarily remove some existing flooring to allow for inspection to demonstrate that the existing internal trap, required water seal and flow characteristics are compatible with its use and that the supply fittings meet the CSA standards.

6. **Chief Building Official's Position**

On the first issue the Respondent submitted that the stack vent for the sewage tank does not meet the appropriate requirements.

Regarding the second, they argued that the slope of the drainage pipe was far from adequate. They noted that the fall should be approximately 8 1/2 inches, not the 2 3/4 provided. He believed that the slope should be increased.

The Respondent noted that the verification of the toilet was impossible because the fixture had no certification markings. Without these he was not able to assess many of the other working components of the subject water closet. In his view, a new toilet with clear certification markings should be installed.

7. **Commission Ruling**

It is the decision of the Building Code Commission

i)that the sewage tank in question is not regulated by the Building Code provided it is vented independently of the vent stack servicing the other appliances in the Building.

And

ii)that the toilet provides sufficiency of compliance with requirements for C.S.A. certification under O.W.R.A. 4.8.1.(1).

And

iii)that the 2" drain pipe provides sufficiency of compliance with the requirements for total fall as per O.W.R.A. 4.8.1.(1) provided evidence of compliance is provided through calculations using the Manning formula for this application.

8. **Reasons**

i)The sewage tank that is vented independent of the plumbing system is considered part of the septic system and not subject to the Building Code.

ii)The toilet being used was manufactured prior to the requirement for certification by C.S.A.

iii)Evidence by the Applicant stated that the toilet has been in use for approximately 6 - 7 years and is functioning satisfactory.

iv)There is an exception to the fall requirement for drain lines.

Agent for the Applicant

RULING

1. **The Applicant**

   The Applicant, Mr. Norman Landry, Construction Manager, The Home Depot, has applied for a building permit under the *Building Code Act, 1992* to construct a shade screen to create a garden centre at The Home Depot, 1900 Baseline Road, Nepean, Ontario .

2. **Description of Construction**

   The Applicant proposes to construct a one storey, 2,612 m2 shade screen to create a garden centre abutting the existing Home Depot building to be used for the sale and display of plant material and agricultural products. The shade screen is proposed to be constructed of a steel structure composed of purlins and arches with a polyethylene cover. The garden centre will abut the main building on one side and a 150 mm (6 in) gap will be maintained between the two structures. The other three sides of the garden centre will be surrounded by a 3.66 metre (12 ft) architectural wrought iron fence. The end portion of the shade screen will not have gables. The garden centre will not be heated.

   The existing Home Depot store will be allowed to have two exits discharging into the garden centre. These exits will be no more than 25% of the required exits and no more than 25% of the required capacity of exits from the Home Depot building. The egress aisles through the garden centre will have a minimum width of 1.1 metre. The garden centre will be provided with a

minimum of two means of egress leading to an open space. The shade screen of the garden centre will be located at least 3 metres, measur ed horizontally, from adjacent buildings on the property or to the property line.

The existing Home Depot building is a single storey, 9,755 m2 structure that is used for the sale and display of home improvement products. The building is of noncombustible construction, including pre-cast concrete exterior walls with a 2 hour fire-resistance rating, except where the existing building meets the garden centre. At this area, the Home Depot structure is provided with a BMEC Authorized sprinkler protected glazed screen with a 2 hour fire-resistance rating, separating it from the garden c entre. The building is equipped with electrically supervised sprinkler and fire alarm systems and there are fire hydrants located adjacent to both the existing building and the garden centre. The sprinkler system and fire alarm system do not extend into the garden centre, however. The exits for the Home Depot structure are located at 60 metre intervals along the perimeter of the building.

The garden centre and existing building are classified as having a Group E - mercantile occupancy.

3. **Dispute**

The issue at dispute between the Applicant and the Respondent is whether the proposed garden centre, with its shade screen, can be considered a separate and temporary structure, such as a tent, and thus be permitted to comply with Subsection 3.1.6. (Tents, Air-Supported Structures and Temporary Structures) of the Ontario Building Code. If the shade screen can be considered as separate and temporary, then the spatial separation requirements of Subsection 3.2.3. (Spatial Separation and Exposure Protecti on of Buildings) apply to the existing Home Depot building, which is located only 150 mm from the garden centre. Further, Sentence 3.1.6.3.(2) requires that all "tents" be located at least 3 metres from an adjacent building.

However, if the shade screen cannot be considered as a temporary and separate structure and is interpreted as a permanent addition to the existing building, other provisions of the OBC, must be applied. These provisions include, but are not limited to Subsection 3.2.2. (Building Size and Construction Relative to Occupancy), Subsection 3.2.4. (Fire Alarm and Detection Systems) and Section 3.4. (Requirements for Exits), then must be applied. As well, depending on this latter interpretation, exiting throug h the garden centre and the increase in travel distance from the Home Depot building are also potential issues.

4. **Provisions of the Building Code**

Sentence 3.1.6.3. Clearance to Other Structures

(1) Except for tents used for camping and other personal uses and except as provided in Sentences (2), (3) and (4), every tent, air-supported structure and temporary structure shall conform to Subsection 3.2.3.

5. **Applicant's Position**

The Applicant submitted that the shade screen, while fitting the definition of a building as found in the Building Code Act since it comprises a roof sheltering an occupancy below, does not have a floor area nor a building area as defined in the OBC because there are no exterior walls. (The Applicant, it appears, does not consider the wrought iron fencing to be a wall.) Based on the openness of the structure and the fact that the shade screens themselves are taken down every winter, the Applicant argues that the garden centre is a temporary structure and is subject to Subsection 3.1.6. of the OBC.

The Applicant also submitted that because the shade screen does not have any exterior walls, it therefore cannot have an exposing building face as defined in the OBC. As such, it is their view that Subsection 3.2.3. is not applicable to the garden centre. They recognize, however, that it does apply to the existing Home Depot building located only 150 mm away. In order

to provide adequate separation between, in their view, what are two distinct buildings, the Applicant is proposing that the Home Depot store meet the OBC standards for a building with a zero metre limiting distance for spatial separation purposes. For a Group E occupancy, Clause 3.2.3.7.(2)(a) requires that the subject exterior wall be of noncombustible construction with a 2 hour fire-resistance rating, and have noncombustible cladding. The Applicant notes that the glazing in the exterior wall of the Home Depot facing the garden centre will provide the required 2 hour resistance rating through the installation of a BMEC Authorized sprinklered window assembly.

Regarding the issue of exiting through the garden centre, the Applicant argues that this is permissible since the structures in question are two separate buildings on the same property and such an egress route is allowed under the OBC. Further, the travel distance within the garden centre can be measured from the exterior wall of the Home Depot.

Finally, the Applicant is proposing that the exit and convenience doors from the Home Depot building into the garden centre will be equipped with close spaced exposure sprinklers on the Home Depot side. The heads will be approximately 2 metres apart and will be connected to the wet ceiling sprinkler system, where the water demand of the close spaced sprinklers will be added. This system is designed to provide a minimum of 3 US gallons per minute per lineal feet of openings.

It is for these reasons that the Applicant believes that the subject garden centre and shade screen is a temporary and separate structure, which is permitted to comply with Subsection 3.1.6. of the OBC and which has provided for adequate spatial separation measures in accordance with Clause 3.2.3.7.(2)(a).

6. **Chief Building Official's Position**

The Respondent offered various possible interpretations of how the proposed garden centre and shade screen could be interpreted under the OBC, including as a temporary structure, a fixed, permanent canopy, as a separate building and as a structure attached to the main Home Depot building. The Respondents were seeking clarification on this matter from the Building Code Commission.

Ultimately, the Respondent submitted that the garden centre could be viewed as a separate and temporary structure, meaning that Subsection 3.1.6. could be applied. However, they did not agree that the 3 metre spatial separation could be waived because there is no exposing building face. The Respondents made comparisons with an open air, multiple storey parking garage and how such a structure can be interpreted as having 100% unprotected openings which therefore requires a 3 metre spatial separation setback.

Lastly, the Respondent noted that a previously Code conforming required exit would now lead directly into the garden centre enclosure and not to an exterior open area.

7. **Commission Ruling**

It is the decision of the Building Code Commission that the temporary and separate structure (shade screen) adjacent to the main building provides sufficiency of compliance with Subsections 3.1.6. and 3.2.3. of the Building Code provided that;

i)Openings facing the shade screen in the main building will be protected by BMEC authorized window assemblies and close spaced sprinklers for doors.

ii)The exterior wall assembly adjacent to the shade screen provides a 2 hr fire separation.

iii)Exiting through the enclosed garden centre fencing will be provided as required under the Building Code.

- **Reasons**

i)The shade screen is considered a temporary structure and subject to the requirements of 3.1.6.

ii)The shade screen area is unheated.

iii)The framing elements for the structure are non combustible.

iv)The shade screen covering will have a flame spread rating of less than 25.

v)The additional sprinkler protection in the main building openings provided additional protection from fire spread.

vi)Fire spread through openings from the exterior is addressed through outside storage provisions in the fire code.

DATE OF RULING
March 4, 1998

APPEARANCES
Mr. Bruce Lasby
Thomasfield Homes Ltd.
Guelph, Ontario
The Applicant

Mr. Bruce Poole
Chief Building Official
City of Guelph, Ontario
The Respondent

RULING

1. The Applicant

Mr. Bruce Lasby, Operations Administrator, Thomasfield Homes Ltd., Guelph, Ontario was issued an order under the Building Code Act, 1992 to rectify the installation of microwave units at certain new residential structures at various sites at 1550 Gordon Street and Lot 67, Plan 856, Hse #56, Guelph, Ontario.

2. Description of Construction

The Applicant has constructed numerous new residential units in the City of Guelph. The construction of the subject units includes complete cabinetry in the kitchens, as well as the installation of certain appliances. The Applicant proposes to install combination microwave oven/hood exhaust units above the stove burners, at a minimum height in accordance with the manufacturers specifications.

The appliances in question are described as standard microwave units with integral exhaust fans and lights mounted on the underside. The exhaust fumes are vented through ducting within the fan hood and

are then are expelled to the upper rear of the microwave, at which point they are forced through standard exhaust ducts. The combination microwave/fan appliances project only 25 to 50 mm (1 to 2 in) beyond the face of the cabinetry.

3. Dispute

The issue at dispute between the Applicant and Respondent is whether the installation of the subject microwave units complies with Article 9.33.2.1. of the Ontario Building Code. This provision requires that a vertical clearance of not less than 750 mm (2 ft, 6 in) must be provided above stove ranges. The Applicant is installing the microwave units as per the manufacturers instructions. The City is not prepared to accept the installation of the microwave units at less than 600 mm (24 in).

4. Provisions of the Ontario Building Code

Sentence 9.33.2.1. Vertical Clearance

1. Except as provided in Sentence(2), a vertical clearance of not less than 750 mm (2 ft 6 in) shall be provided above the elements or burners of electric-and gas-fired domestic ranges.

5. Applicant's Position

The Applicant submitted that the combination microwave/hood fan units are being installed properly - in accordance with the manufacturers specifications. In fact, they are installing most of the subject appliances at approximately 475 to 500 mm (19 to 20 in) above the burner, at least 125 mm (5 in) higher than the manufacturers' permissible minimum installation.

In their view, the OBC and Article 9.33.2.1. in particular, refer only to the clearance of the combustible cabinets above the surface of the cooktop. They also note that the local area fire departments do not have standards regulating the clearance between stoves and microwaves. This is because, as the Applicant argues, the issue of clearance between these two appliances is set by the manufacturers who have had the installation configurations tested by accredited testing agencies. (The Applicant provided material from UL and CSA which indicated that the cooktop to microwave height should be done in accordance with the manufacturer's installation instructions.) It is not an area that is covered by government regulation. They do point out, however, that the proposed installation of the combination microwave/hood fan units is approved by Ontario Hydro.

The applicant further argues that installing the microwave units at the location required by the Respondent would dangerous since users would be required to remove hot items from an unsafe height. In the case of children, they would handling hot food above their heads.

6. Chief Building Official's Position

The Respondent submitted that the proposed installation of the subject appliances do not conform to OBC Article 9.33.2.1. In their view, the Code is clear in its requirements; 750 mm (30 in) clearance above a range, or with a metal exhaust fan hood which extends 125 mm (5 in) beyond the face of the cabinetry the clearance can then be reduced to 600 mm (24 in), as per Sentence 9.33.2.1.(2). Under no circumstance does the Code allow a reduction of clearance to less than 600 mm (24 in).

The Respondent indicated that they had contacted the CSA and had inquired about the testing conducted on the microwave to cooktop clearance. They noted that the relevant test had only used full radiant heat to simulate the cooking elements. Testing with flame was not done. This discrepancy, the Respondent believes, is serious enough to ignore the manufacturer's installation specifications and rely upon the additional clearance set out in the OBC.

The Respondent also submitted that discussions with the Guelph Fire Prevention Office revealed that a number of fires have occurred in kitchens due cooking accidents or grease build up and are then propagated by the cabinetry. By locating the microwave closer to the cooktop, they argue that there is an increased chance for cooking accidents (fire ignition and scalding) since inadequate working space would be provided. As well, the closer proximity may cause greater grease build up to occur.

They also note that the pending 1997 version of the OBC has been amended to clarify this provision that a 750 mm (30 in) clearance is required to any building finish unless protection measures are provided. But in no case can the clearance be less than 600 mm (24 in).

Lastly, the Respondent recommends that the subject appliance make application to the Building Materials Evaluations Commission to have the product assessed and possibly tested. Otherwise, they feel that the proposed microwave installation represents a potential reduction of current safety standards which may place occupants and property in these residential units at risk.

7. Commission Ruling

It is the decision of the Building Code Commission that the installation of the combination microwave and exterior vented hood fan with clearances above the top of the stove burner installed in accordance with the manufacturers instructions provides sufficiency of compliance with Article 9.33.2.1. of the Ontario Building Code.

8. Reasons

i. The clearances required in Article 9.33.2.1. of the Building Code are clarified in the 1997 Building Code to be specific to framing, finishes and cabinets.
ii. The certification agencies for electrical hazards require installation instructions including clearances to stove burners.
iii. These products have been available for a period of time.

RULING

1. **The Applicant**

   Mr. Mike Ralph, Property Manager, Ellis Don Construction Ltd., has applied for a building permit under the Building Code Act, 1992 to construct a twelve cinema, movie theatre complex, known as the Britannia 12-Plex Theatre at 3090 Carling Avenue, Nepean, Ontario.

2. **Description of Construction**

   The Applicant proposes to construct a two storey (plus mezzanines), multi-theatre, movie complex containing twelve cinemas. The structure has a building area of roughly 6, 350 m2. It is proposed to be circular in shape, with the cinemas located at the p erimeter surrounding a central lobby with three entrances and an intermediate mezzanine level between the first and second storeys. The lobby contains ticket taking areas, concession facilities and ancillary games and party rooms.

   Access to the six larger cinemas, is via the mezzanine level, whereas access to the smaller theatres is obtained directly from the lobby. For all cinemas, access is through entrance

vomitories from either the lobby or mezzanine. The second storey is use d as the common projection level for all cinemas.

The larger cinemas have occupant loads ranging from 300 persons to just over 400 persons. The smaller ones have occupant loads of slightly over 200 persons. The occupant load for the entire building is approximately 3,000 persons.

The building is constructed of noncombustible construction. All of the cinemas are fire separated from the rest of the building, including the projection level by a 1 hour rated fire separation. The common projection level is separated by a two hour fir e separation from the lobby area.

The building is equipped with a sprinkler system and a two-stage fire alarm system. The structure is classified as having Group A - Division 1 - (motion picture theatres) major occupancy.

The Applicant is also proposing that the central lobby of the subject structure, unlike the surrounding cinemas, have no suspended ceiling. It is proposed that the roof structure remain fully exposed to enhance the impression of the size of the lobby. A s a result, the lobby is to have a high ceiling, measured at 16.7 metres above grade. The rest of the building generally has a ceiling height of 14 metres.

3. **Dispute**

The issue at dispute between the Applicant and the Respondent is whether the proposed multi-theatre complex is required to install a standpipe and hose system in accordance with Article 3.2.9.1. of the Ontario Building Code. This provision requires that structures with a ceiling height of more than 14 metres be equipped with a standpipe and hose system. For buildings that have a building area greater than 4,000 m2, as in this case, the OBC standards for standpipe systems further require that 65 mm hose connections for the use of Fire Departments and 38 mm connections with 30 metres of hose be installed as well. In the subject building, most of the height between grade and the ceiling is roughly only 14 metres, however, the lobby area does exceed the p ermitted height.

4. **Provisions of the Building Code**

3.2.9.1. Where Required

(1) Except as provided in Article 3.2.9.2., a standpipe and hose system, shall be installed in every building that

(a) is more than (i) 3 storey in building height, or (ii) 14 m (45 ft 11 in) in height measured between grade and the ceiling of the uppermost storey,(b) is greater in building area than the area shown in Table 3.2.9.A. for the applicable building height shown in the Table where the building (i) is not sprinklered, and (ii) is not more than 14 m (45 m 11 in) high measured between grade and the ceiling of the top storey, or(c) contains more than one storey below grade

5. **Applicant's Position**

In order to provide sufficiency of compliance with Article 3.2.9.1., the Applicant proposed to install a standpipe and hose system for the lobby of the theatre complex only. The proposal calls for the installation of hose connections consisting of 65 mm connections with 38 mm adaptors at each of the three lobby entrances. This would mean that all areas of the lobby would be within 33 metres of one of the three hose connections. In the Applicant's view, the proposal to provide a standpipe and hose system for this area only is justified since if they were to provide a suspended ceiling at a height of 14 metres in the lobby, they would be able to avoid the requirement for a standpipe system altogether.

By way of rationale for this proposal, the Applicant argues that since only the lobby area exceeds 14 metres in height, it should be the only portion of the building to be equipped with a standpipe system. The standpipe connections in the lobby area wil l be placed at each of the three entrances, one of which has a two hour fire resistance rating, thus providing easy access for fire fighters. Since the entrances are equally spaced access to all parts of the lobby may be possible during a fire. The sta ndpipe system in the lobby, the Applicant claims, will therefore act as a supplement to the sprinkler system to combat the spread of fire.

In the cinemas, which, under the proposed partial standpipe system, would not be covered, the Applicant argues that the standpipe system would be less effective. As Fire Department personnel prefer safe staging to prepare for fire attack, entering the ci nemas from the lobby is less desirable than obtaining fire fighting access directly from the exterior, which all of the cinemas have. This exterior access is made possible by the Fire Department access route which completely encircles the building. Again, within the cinemas the sprinkler system would also do much of the fire combatting.

The Applicant also noted that the option of lowering the lobby ceiling has its drawbacks in terms of fire safety as well. They point out that the suspended ceiling would act as a large concealed space not readily accessible for fire fighting. Lowering t he ceiling would also reduce the volume of space within which smoke can accumulate. As well, lowering the ceiling does not reduce the combustible load or potential fire hazards in the lobby area. Further, all interior finishes have a flame spread rating less than the allowed maximum found in the OBC. The combustible load in the lobby, therefore, is relatively low compare d to other single storey, high bay buildings such as warehouses, the Applicant noted.

Finally, the Applicant noted that the theatre staff will be trained in emergency evacuation procedures and first stage fire fighting. The staff will be trained to abandon fire fighting, however, when the fire develops beyond fire stage, which would mean that the reduced diameter hoses would not likely even be used.

It is for these reasons that the Applicant believes that the proposal provides sufficiency of compliance with Article 3.2.9.1. of the OBC.

6. **Chief Building Official's Position**

The Respondent submitted that the proposed ceiling height of 16.7 metres in the lobby area necessitates that the building be equipped with a standpipe and hose system in accordance with 3.2.9.1. As far as the Applicant's sufficiency of compliance proposa l was concerned, the municipality rejected it on the basis that the Building Code does not offer a mechanism that would allow for a relaxation or relief of the requirements for a standpipe and hose system.

Further, the Respondent believed that the Applicant's proposal could not be considered as providing equivalency because no rational nor other evaluations were submitted to establish past performance that might have enabled the municipality to determine wh ether the level of performance would be decreased.

7. **Commission Ruling**

It is the decision of the Building Code Commission that not providing a standpipe and hose system in the theatre complex provides sufficiency of compliance with the requirements of the Building Code.

8. **Reasons**

i) Hose connections consisting of 65 mm connections with 38 mm adapters at each of the three lobby entrances will be provided.

ii) The Building Code requirement for a standpipe and hose system for buildings with grade to ceiling heights more than 14 m, is exceeded only in the lobby (at a height of 17 m). All other areas within the theatre complex do not exceed 14 m in height.

iii) Evidence submitted suggests the proposed lobby ceiling height increases time occupants are not exposed to smoke by approximately 11%.

iv) All cinema areas are separated from the rest of the building by 1 hour fire separations.

v) Exits are provided from the cinemas directly to grade.

vi) The building is fully sprinklered.

vii) The building is equipped with a 2-stage fire alarm system, with all alarm systems connected to a central station.

The Respondent

RULING

1. **The Applicant**

   Mr. Peter Hallman, President, Hallman Eldercare (Waterloo) Inc., applied for a building permit under the Building Code Act, 1992 to construct a low-rise, care home facility known as Terrace on the Square at 100 Caroline Street, Waterloo, Ontario.

2. **Description of Construction**

   The Applicant proposes to construct a four storey (plus basement), multi-unit, care home facility intended for senior citizens. The structure is classified as Group C - residential major occupancy. The building is constructed of combustible construction and has a building area of 1,175 m2. It is equipped with a sprinkler system, a fire alarm system and a standpipe and hose system.

   As part of the design of the subject structure, the Applicant proposes to include "re-entrant corners" on the second, third and fourth floors. A re-entrant corner is defined as when the exterior walls of two adjacent units subtend 90 degrees from one another. In the present

situation, the closest edges of the window openings of the re-entrant corner units are separated by a distance of 1.5 m on the second and third floors and 0.8 m on the fourth floor.

3. **Dispute**

The issue at dispute between the Applicant and the Respondent is whether the proposed separations of 1.5 m and 1.75 m for the re-entrant corner openings comply with the requirements of OBC Article 3.2.3.14. This provision of the OBC sets out the formula for fire compartments facing each other in the same building (i.e., units at re-entrant corners) and is used to calculate the limiting distances for exposing building faces. Article 3.2.3.14. also requires that the exterior wall of each fire compartment facing each other must have a fire-resistance rating at least equal to that of the fire separation between the two fire compartments.

4. **Provisions of the Building Code**

Article 3.2.3.14. Wall Exposed to Another Wall (1) Except as provided in Sentences 3.2.3.13.(1) and 3.2.3.20.(4), where an opening in an exterior wall of a fire compartment is exposed to an opening in the exterior wall of another fire compartment, and the planes of the 2 walls are parallel or at an angle of less than 135o, measured from the exterior of the building, the openings in the 2 fire compartments shall be separated by a distance at least equal to D_o where

D_o = 2D - (0 x D), but in no case less than
90
1 m (3 ft 3 in)

where

D= the greater required limiting distance for the exposing building faces of the 2 fire compartments, and
0= the angle made by the intersecting planes of the exposing building faces of the 2 fire compartments, (in the case where the exterior walls are parallel and face each other, 0 = 0^o).

- **Applicant's Position**

The Applicant submitted that the proposed distances between the unprotected openings complies with Article 3.2.3.14. of the OBC. On the basis that the exposing building face has a maximum area of 10 m2, 18 percent unprotected openings, and that the building is sprinklered they derive a limiting distance less than the 1.5 m and 0.8 m distances proposed. Their calculations, in effect, reduce the

percentage of unprotected openings from 18 to 9 percent because the building is sprinklered. The assumption used in this reduction is that the usual benefit of installing sprinklers, a doubling of openings in accordance with Article 3.2.3.11., can instead be applied towards a reduction in the limiting distance. As such, using 9 percent as the area of unprotected openings, the Applicant calculates the limiting distance in this situation to be 1.35 m.

The Applicant also notes that the proposed distances of 1.5 m and 0.8 m would also meet the standards set out in the 1997 version of the OBC, which adds a provision that allows that the spatial separations in the situation at issue to be waived because the building is sprinklered.

(Sentence 3.2.3.13.(3). It is for these reasons that the Applicant believes that they comply with Article 3.2.3.14. of the OBC.

- **Chief Building Official's Position**

The Respondent initially submitted that the proposed limiting distance does not meet the requirements of Article 3.2.3.14. Table 3.2.3.A stipulates that 2 m is the necessary distance between the proposed openings. In their view, the Code does not allow the assumption made by the Applicant regarding reducing limiting distance. Under Article 3.2.3.11., openings (which are presumably appropriately spaced from one another) are permitted to be increased in size, but nowhere, they argue, does it allow for distances to be reduced. In light of the 1997 Code, the municipality had no objection.

- **Commission Ruling**

It is the decision of the Building Code Commission that the proposed distance between openings demonstrates sufficiency of compliance to the Ontario Building Code.

- **Reasons**

i) The building is fully sprinklered and exposure between fire compartments is minimized. ii) The 1997 edition of the Building Code waives the requirements for spatial separation between different fire compartments having unprotected openings meeting at an angle of less than 135o when the building is fully sprinklered.

iii) The municipality has no objection to accepting compliance under the 1997 Building Code.

The Respondent

RULING

1. **The Applicant**

   Mr. Rae Gardner, President, Rae Gardner Construction, is the holder of a building permit under the *Building Code Act, 1992* for the construction of a seasonal residential building, known as the Robert Lantos cottage at Part Lot 13, Concession 1, Township of Humphrey, District of Parry Sound, Ontario.

2. **Description of Construction**

   The Applicant has erected two seasonal residential buildings on the subject property; a two storey structure intended for use as a main cottage, and a two storey boathouse built on the water. The structures are classified as Group C - residential major occupancies. Both buildings are constructed of combustible construction.

   On both buildings, the Applicant has constructed guards and railings in various locations. The main cottage building has a large semi-circular shaped deck at the front with stairs and

associated railings leading to grade level. The boathouse has an exterior stair with railings from grade level serving the second floor; the second floor has an enclosed porch/deck area recessed into one corner of the second floor surrounded by a guard. All of the guards and stair railings have been built with natural and therefore irregularly shaped cedar logs.

3. **Dispute**

The issue at dispute between the Applicant and the Respondent is whether the as built guards and railings constructed of natural logs provides sufficiency of compliance with Sentence 9.8.8.2.(1) and Article 9.8.8.4. Respectively, these provisions of the Building Code provide standards for the height of guards around balconies and the spacing of the openings in the guard. The irregular shaped nature of the cedar logs has apparently made compliance with these requirements difficult. In some parts, the guard is only 1,030 mm (40 1/2 in), which is 40 mm (1 1/2 in) too low, whereas the spacing between the pickets varies between 152 mm (6 in) and 114 mm (4 1/2 in), which ranges from 13 mm (1/2 in) to 52 mm (2 in) too wide.

4. **Provisions of the Building Code**

9.8.8.2. - Height of Guards

(1) Except as provided in Sentences (2) to (5), all guards, including those for balconies, shall be at least 1 070 mm (3 ft 6 in) high.

9.8.8.4. Openings in Guards. Openings through a guard on balconies, porches, and decks, an exit stair, or stairs, landing and the floor level around a stairwell in a dwelling unit, shall be of a size so as to prevent the passage of a spherical object having a diameter of 100 mm (4 in) in residential occupancies and 200 mm (7-7/8 in) in other occupancies, unless it can be shown that the location and size of such openings which exceed these limits do not represent a hazard.

5. **Applicant's Position**

The Applicant submitted that the height of the guards and the spacing between the pickets complies with Sentence 9.8.8.2.(1) and Article 9.8.8.4. of the OBC. In their view, the construction material used for the guards, railings and pickets, natural cedar logs, made it difficult to maintain precise and uniform heights and spacings. As a result, they argue that the as built guards and railings are within allowable variations and should be construed as providing sufficiency of compliance with the Building Code.

6. **Chief Building Official's Position**

   The Respondent submitted that the guards and railings, as constructed, do not meet the relevant provisions of the Building Code. They argue that the Building Code is very specific with regard to guard heights and openings through guards and the subject construction does not meet the prescribed standards.

7. **Commission Ruling**

   It is the decision of the Building Code Commission that the guards do not conform to the requirements of the Building Code.

   Guard height should be measured from grade at the base of the landing or deck to the top of the guard.

8. **Reasons**

   i) The boathouse guards do not meet the minimum 1070 mm height as required by the Building Code.

   ii) Openings through guards exceed the maximum size permitted by the Building Code to prevent the passage of a 100 mm diameter spherical object.

   iii) Sufficiency of compliance was not demonstrated.

For the Respondent

RULING

1. **The Applicant**

   Mr. Richard Gaukel, Vice President, Support Services, BFC Utilities, Toronto (Scarborough), Ontario has been issued an order under the Building Code Act, 1992 to comply regarding the removal of approximately 700 metres of 200 mm polyethylene pipe used as a water main at the Seneca College of Applied Arts and Technology, 1750 Finch Avenue East, Toronto (North York), Ontario.

2. **Description of Construction**

   The Applicant proposed to install 1,535 metres of PVC pipe to serve as the replacement water main supplying fire hydrants and multiple buildings at the Newham Campus at Seneca College in North York. Prior to installation, discussions occurred between the Applicant and the municipality regarding the possibility of using the subject polyethylene pipe instead. At that point, it was revealed that the parties had differing views about whether the polyethylene pipe complied with the appropriate OBC standards. After 700 metres of PVC pipe had been laid, the

Applicant proposed to use polyethylene pipe for the remainder of the installation. On December 10, 1997, the municipality issued an order to comply with Part 7 of the Ontario Building Code. On January 9, 1998, the Applicant had the subject pipe tested for hydrostatic pressure and leakage to demonstrate its compliance. The test results did not resolve the issue. In the meantime, work continued at the site and the Applicant made an application to the BCC.

3. **Dispute**

The issue at dispute between the Applicant and Respondent is whether the subject pipe meets the standards cited in the Ontario Building Code or meets an acceptable alternate test standard as equivalent. Sentence 7.2.5.5.(1) requires that water pipes be certified to CAN/CSA-B137.1 and that they have a rated working pressure of 1034 kPa (150 psi). A product which does not meet the test standards under Article 7.2.5.5. but which has met other standards can be considered if those alternate tests are shown to be comparable to those described in the OBC. Without demonstrating compliance with the standards set out in the Code or comparable ones, the pipe may have to be replaced.

4. **Provisions of the Ontario Building Code**

Article 2.6.4.1. Alternate Test Standards

The results of tests based on standards other than as described in this Code may be used if the alternate standard provides pipe having comparable performance.

Sentence 7.2.5.5. Polyethylene Water Pipe and Fittings

(1) Polyethylene water pipe and fittings shall be certified to CAN/CSA-B137.1, "Polyethylene Pipe, Tubing and Fittings for Cold Water Pressure Services", Series 160, and shall have a rated working pressure of 1034 kPa (150 psi) or more.

5. **Applicant's Position**

The Applicant submitted that their pipe cannot meet CSA B137.1 since that standard covers only pipes up to 150 mm (6 in) in diameter whereas the subject pipe has a diameter of 200 mm (8 in). Since there is no CSA standard to cover the size range supplied on this project, it is their belief that, under Article 2.6.4.1., other comparable standards may be used. In terms of other standards, they claim that the pipe is certified under the National Sanitation Foundation 61 standard and

meets the American Water Works Association C906 standard for potable water use. The Applicant also notes that the manufacturer is ISO 9001 approved.

The applicant further argues that there is a considerable amount of this product installed in water applications throughout the province. Polyethylene, they note, has an excellent record in water applications, with many years of proven performance.

6. **Chief Building Official's Position**

The Respondent submitted that the installed polyethylene pipe at the Seneca College site does not meet the CSA B137.1 standard. They note that the Series 160, under that standard, is required to have a rated working pressure of 1034 kPa (150 psi). The Respondent argues that the installed pipe has a rated working pressure of only 100 psi. As a result, they believe that the subject pipe does not meet standards set out in the Code, nor does it meet equivalent tests of other standards and testing agencies.

7. **Commission Ruling**

It is the decision of the Building Code Commission that the 8" P.E. piping used in the water main provides sufficiency of compliance with Article 7.2.5.5 of the Building Code.

8. **Reasons**

i) The 700 linear m of piping has been tested to 150 psi in accordance with the Tender Documents.

ii) The product diameter exceeds the maximum size specified for HDPE pipe under C.S.A.B 137.1 (up to 6" in diameter), but is approved the A.W.W.A. C 906 standard for this use.

iii) The working pressure for the system is approximately 70 psi and the product can accommodate the 50% increase for repetitive surges.

iv) The product has been used in other applications without negative impact.

The Respondent

RULING

1. **The Applicant**

   Mr. Louis Lortie, Project Manager, Conseil des ecoles catholiques de langue francaise d'Ottawa-Carleton, has applied for a building permit under the *Building Code Act, 1992* to construct an elementary school at Stonehaven Drive, Kanata, Ontario.

2. **Description of Construction**

   The Applicant proposes to construct a one storey, 16 classroom elementary school with a building area of 4,080 m2. The building is to be constructed of noncombustible construction. It will be equipped with a sprinkler system and a fire alarm system. The total occupant load of the building is projected to be 627 persons. The building is described as having a Group A, Division 2 major occupancy.

   The proposed layout of the structure shows that certain classrooms, specifically C01, C03, C04, C05, C09, C10, C11, C13 and L02, have egress distances slightly exceeding the maximum of 15

m allowed under the OBC. The proposed travel distance from the sub ject classrooms ranges from 15.9 m (C03) to 17.9 m (C13).

3. **Dispute**

The issue at dispute between the Applicant and Respondent is whether the egress distances, which slightly exceed the 15 m allowed, in a building that is sprinklered, provide sufficiency of compliance with Article 3.3.1.5. of the Ontario Building Code. Se ntence 3.3.1.5.(1) and Table 3.3.1.A. set out that for Group A occupancies the maximum distance to an egress doorway is 15 m.

4. **Provisions of the Ontario Building Code**

Article 3.3.1.5 Egress Facilities

(1) Every room and every suite shall have 2 egress doorways placed in such a manner that one doorway could provide egress from the room or suite as required in Article 3.3.1.3. if the other doorway becomes inaccessible to the occupants due to a fire which might originate in the room or suite.

(a) where the area of the room or suite is more than 15 m2 (161 ft2) and (i) contains a high hazard industrial occupancy, or (ii) is a hazardous room,(b) which is intended for an occupant load of more than 60 persons, (c) where the area of a room or suite, or the distance measured from any point within the room or suite to the nearest egress doorway is more than the values shown in Table 3.3.1.A., or (d) where the room is hazardous classroom having an area more than 100 m2 (1080 ft2) and is in an elementary or secondary school.

5. **Applicant's Position**

The Applicant submitted that the egress distances provide sufficiency of compliance because the excess travel distances are only marginal, ranging from 0.9 m to 2.9 m. They further argue that the pending 1997 version of the OBC relaxes the 15 m travel di stance standard to 25 m if the floor area is sprinklered. The Applicant notes that the proposed school will be sprinklered.

6. **Chief Building Official's Position**

The Respondent submitted that the proposed travel distances exceed those allowed in the current OBC. As they note, in the proposed school 9 of the 16 classrooms exceed the allowed travel

distance of 15 m when measured along the natural travel path. Cons idering the building is to be used as an elementary school they were less willing to be flexible on the excess travel distances.

The municipality recognizes the future Code change, however, they indicate that approving applications on the basis of future OBC provisions is not within their jurisdiction.

The municipality also had some concerns regarding the method of measurement to calculate the travel distance. They requested clarification from the Commission on the best method of measurement.

7. **Commission Ruling**

It is the decision of the Building Code Commission that the proposed egress distance provides sufficiency of compliance with Article 3.3.1.3. of the Building Code.

8. **Reasons**

i) The travel distance is only marginally over the 15 m cited in the Table 3.3.1.A. of the 1990 Ontario Building Code when measured one foot from the perimeters walls and is in compliance when measured in a straight line from the most remote point.

ii) Proposed changes to the 1997 Ontario Building Code gazetted but not in effect at this time would increase the travel distance permitted in this application to 25 m for sprinklered buildings, and the building is sprinklered throughout.

Dated at Toronto this 12th day in the month of February in the year 1998 for application number 1997-80.

RULING

1. **The Applicant**

   Mr. Chris Bretton, President, Bretton Imported Cars has applied for a building permit under the *Building Code Act, 1992* to construct a one storey addition to an existing building which is currently used as an automobile showroom at 1239 Plains Road East, Burlington, Ontario.

2. **Description of Construction**

   The Applicant proposes to renovate an existing 300.8 m2, one storey building by adding a 221.6 m2 one storey addition. The total building area of the completed structure will be 522.4 m2. The proposed addition will be constructed of combustible construction and will be open internally to the existing building. The building is not equipped with a sprinkler or standpipe system. The structure is currently being used as an automobile showroom and repair garage and this occupancy is intended to be expanded after the renovation. The building is classified as having an F - 2 (medium hazard industrial) major occupancy.

   The Applicant intends to install three large (3.05 m by 3.05 m) overhead door openings on the rear wall of the new addition for service bays. (The dimensions of the rear wall are 13.72 m in

length and 4.85 m in height.) This wall, however, is located approximately 7.6 m from the rear property line. Abutting the subject property to the rear are the Canadian National Railway lands. The Applicant is proposing that since the property to the rear is a railway, the limiting distance can be calculated differently, meaning that the three proposed overhead doors need not be 1.5 h rated as would be required if 7.6 m was used in the limiting distance calculation.

3. **Dispute**

The issue at dispute between the Applicant and Respondent is whether the limiting distance between the subject addition and the abutting property is 7.6 m, as measured to the property line. Or, assuming the railway property will never be built upon, can the limiting distance be calculated using the centre of railroad property, which would be 21.32 metres. (It is 13.72 m from the rear property line of the Applicant's property to the centre line of the railway lands.) The difference between these two types of calculations has a direct impact on the amount of unprotected openings the Applicant is allowed and what level of fire resistance ratings the closures in the openings must meet. Article 3.2.3.1. and Table 3.2.3. set out the relationship between exposing building faces, limiting distances and amount of unprotected openings.

4. **Provisions of the Ontario Building Code**

Article 3.2.3.1. Limited Distance and Area of Unprotected Openings

(1) Except as provided in Articles 3.2.3.9. to 3.2.3.11, the area of unprotected openings shall not be more than that set forth in Tables 3.2.3.A. or 3.2.3.B. for the limiting distance applicable to the exposing building face under consideration. (See A-3, Fire Fighting Assumptions in Appendix A.)

5. **Applicant's Position**

The Applicant submitted that because of the railway property to the rear of their proposed addition, the limiting distances should be calculated on the centre line of the railway property.

They make this argument on the basis that the railway property will, in all probability, never have a building constructed on it. They argue that this would permit the installation of standard insulated doors rather than 1.5 h fire-rated doors. The Applicant notes that they are willing to put on the title of their property a clause requiring compliance with the OBC with respect to the spatial separation should the use of the adjoining property change from being a railway.

6. **Chief Building Official's Position**

The Respondent submitted that the rear property line should be used as the reference point for the limiting distance calculations for the subject building and a centre point of the abutting CN Rail property. In their view, railway lines are to be treated not as roads, but as regular properties. The reasons for this approach are that rail cars cannot be moved easily and they may contain combustible or hazardous materials. As a result, the common property line between any property and a rail line property should be taken as the reference point.

The Respondents further add that the 1997 edition of the OBC allows parties to vary from the prescribed limiting distance standards with a registration of a limiting distance agreement on tile of both properties. In the case at hand, however, they note that CN Rail has not offered to place such a restriction on their property. The Respondent believes such registration is not appropriate for railway lines.

Finally, they note that the building permit was issued on the understanding that the 1.5 hour fire-rated doors would be installed prior to occupancy and that the application to the BCC was made only after the issuance of the building permit.

7. **Commission Ruling**

It is the decision of the Building Code Commission that the protection of openings in the exterior rear wall facing the property line provides sufficiency of compliance with Section 3.2.3. of the Building Code provided that -

Sentence 3.2.3.1.(8) The required limiting distance for an exposing building face is permitted to be measured to a point beyond the property line that is not the centre line of a street, lane or public thoroughfare if

(a) the owners of the properties on which the limiting distance is measured and the municipality enter into an agreement in which such owners agree that

(i) each owner covenants that, for the benefit of land owned by the other covenants, the owner will not construct a building on his or her property unless the limiting distance for exposing building faces in respect of the proposed construction is measured in accordance with the agreement.

(ii) the covenants contained in the agreement are intended to run with the lands, and the agreement shall be binding on the parties and their respective heirs, executors, administrators, successors and assigns.

(iii) the agreement shall not be amended or deleted from title without the consent of the municipality, and

(iv) they will comply with such other conditions as the municipality considers necessary, including indemnification of the municipality by the other parties, and

(b) the agreement referred to in Clause (a) is registered against the title of the properties to which it applies.

(9) Where an agreement referred to in Sentence (8) is registered against the title of a property, the limiting distance for exposing building faces shall be measured to the point referred to in the agreement.

OR

B) The building is sprinklered throughout.

8. **Reasons**

i) The proposed amendments permit extending limiting distance measurements to adjacent property with the consent of both parties registered on title, while respecting the rights of the parties.

ii) Sprinkler protection would provide additional protection and increase the permitted openings.

RULING

1. **The Applicant**

   Mr. Bryan Coleman, President, Shutters Residential Corporation was issued a building permit under the *Building Code Act, 1992* to construct three new, four storey townhouse residential units at Wyndham Terrace Residences, 235, 237 and 239 Church Str eet, Oakville, Ontario.

2. **Description of Construction**

   The Applicant proposes to construct three identical, four storey, attached townhouse residential units. Each unit has a building area of 82 m2 (882 ft2), including the below grade (basement) level. The units are constructed of noncombustible constructio n. Each unit will be equipped with an interconnected smoke detection and fire alarm system and a sprinkler system.

   Since the units are considered to be four storeys, but have only one exit on grade level, the Applicants also propose to create a fire separation between the second and third floors by installing a self-closing and self-latching door. As well, a balcony will be provided from the third floor having a circular stair to the second level terrace. The terrace measures approximately 5.8 m by 5 m and is 3 m above grade.

3. **Dispute**

The issue at dispute between the Applicant and Respondent is whether the proposed measures provide sufficiency of compliance with Sentence 3.3.4.4.(3) of the Ontario Building Code, in lieu of adequate egress from the fourth storey. Sentence 3.3.4.4.(3) o f the Building Code allows a dwelling to have only one exit as long as it is not necessary to travel more than one storey up or down to reach that exit. In the subject building, the fourth floor is three levels above the exit at grade level.

4. **Provisions of the Building Code**

Sentence 3.3.4.4. Egress from Dwelling Units

(3) A single exit is permitted from a dwelling unit provided the exit is an exterior doorway not more than 1.5 m (4 ft 11 in) above adjacent ground level and (a) it is not necessary to travel up or down more than 1 storey to reach the exit door, or

(b) the uppermost floor level opens to a balcony not more than 6 m (19 ft 8 in) above adjacent ground level.

5. **Applicant's Position**

The Applicant submitted that the units, as designed, will provide sufficiency of compliance for the fourth floor egress. The Applicants demonstrate that they are providing several compensating measures to mitigate the fact that the fourth floor is three storeys above the exit, which is not permitted under 3.3.4.4.(3). They are constructing the units of noncombustible construction which is above the Code requirements for this type of building.

The noncombustible construction will provide less fuel for a fire and a higher level of compartmentalization, they note. The floors will provide a minimum one hour fire resistance rating. Further, the individual units are separated from each other and f rom the adjoining three storey buildings by a separation with a two hour fire resistance rating. The Applicants argue that this additional compartmentalization will afford occupants greater time to evacuate.

The units are also to be equipped with a residential sprinkler system. The Applicants note that the addition of sprinklers will provide an effective safety measure. It is anticipated that the sprinklers would certainly contain any fire and would probabl y extinguish one. They would also offer a degree of smoke control. The balconies on each level, save for the basement, would also

provide equivalent smoke control as balconies on high-rise residential buildings consistent with Article 3.2.6.6.

As well, there is a further containment measure, a self closing and self latching door, which has been provided on the second floor. This has the effect of separating the individual units into two fire compartments, preventing smoke migration and thus al lowing extra time for the third and fourth floor occupants to use the balcony and exterior stairs as egress.

The Applicants also point out the units are to be equipped with interconnected smoke detector systems. This system will offer occupants early warning in the event of a fire. This additional time, the Applicants believe, will provide occupants on the upp er floors the opportunity to assess the danger and to evacuate by the exterior stairs, if necessary.

In terms of egress options, the Applicants also argue that the aforementioned balconies and exterior stairs provide a second means of egress for the unit, serving especially the third and fourth floors. The Applicant notes that occupants of the third and fourth floors can access the third floor balcony and then descend the exterior stair. This brings them to an area of refuge, the ground floor terrace. Once on the terrace, occupants have the choice of waiting for the fire department or negotiating the 3 m drop to grade level.

The Applicants provided evacuation data demonstrating favourable egress times for the subject unit in comparison to other structures also governed by these provisions of the Building Code. For example, the evacuation of the proposed units by a disabled p erson would take 2.5 minutes. For a 1,200 m2 unit (the maximum size allowed under Article 3.2.2.36.), the egress time for a disabled person would be 3.1 minutes. For a high-rise building the evacuation time to the exterior by a disabled person would be 7 minutes.

For the reasons discussed above, the Applicant believes that the proposed measures provide sufficiency of compliance with Sentence 3.3.4.4.(3) regarding the fourth floor egress.

6. **Chief Building Official's Position**

The Respondent submitted that the proposed residential units do not comply with Part 9 nor Part 3 of the Building Code. The units do not conform to Sentence 3.3.4.4.(3), in particular. In a four storey structure, they argue, with only one exit at grade level serving that floor, the ground floor, and the third floor, the fourth floor is not adequately served in terms of exits. The Respondent

believes that this situation may cause danger for the units occupants due to the excess travel distance.

7. **Commission Ruling**

It is the decision of the Building Code Commission that the proposed measures for sprinklers, fire alarm, fire separation and egress provide sufficiency of compliance with Sentence 3.3.4.4.(3) of the Building Code, provided that

i) An additional stairway is provided from the 3rd floor balcony to act as an alternate means of egress to the terrace, and

ii) The fire door at the 3rd floor stairway is equipped with a hold open device that will operate to close the door on activation of the fire alarm system.

8. **Reasons**

i) The building is sprinklered throughout.

ii) A fire alarm system with smoke detectors is provided at each floor level.

iii) A fire separation is provided to separate floors 1 & 2 from floors 3 & 4.

iv) The building is of non-combustible construction and adjacent dwelling units are separated by a 2 hr fire separation.

v) Egress from the 4th floor is provided by access to a balcony on the 3rd floor level which has 2 means of access to the terrace.

vi) The rooms on the 4th floor have access to a balcony.

vii) Time based egress analysis indicates that the time to egress is within acceptable limits.

Dated at Toronto this 15th day in the month of January 1998 for application number 1997-77.

RULING

1. **The Applicant**

   Mr. Jeff Davie and Mrs. Louisa Davie, Property Owners, were issued a building permit under the *Building Code Act, 1992* to demolish an existing cottage and to construct a new residence at Lot 14, Plan 674, 276-278 Shorelane, Town of Wasaga Beach, On tario.

2. **Description of Construction**

   The Applicants are constructing a three storey, residence with a total building area of 185 m2 (2,000 ft2). The building, which is substantially completed, is constructed of combustible construction. The building, however, has not been equipped with ven tilation in accordance with Subsection 9.32.3. of the Building Code.

3. **Dispute**

The issue at dispute between the Applicants and Respondent is whether the subject building is required to provide full heating and ventilation systems. The Applicants believed they were constructing the residence in accordance with Subsection 9.36.2 of t he Building Code, which sets out the requirements for cottage construction. The Respondents, on the other hand, view the structure as a year-round residential dwelling.

4. **Provisions of the Building Code**

9.32.1.2 Mechanical Ventilation for Dwelling Units. Every dwelling unit that is supplied with electrical power shall be provided with a mechanical ventilation system in accordance with Subsection 9.32.3.

9.36.2.1 Exclusions

(1) Except as provided in Article 9.36.3.1. and Subsection 9.10.15., building used or intended to be used as seasonal recreational buildings need not comply with Sections 9.5. to 9.7. and 9.9. to 9.11.

(2) Flooring need not comply with Section 9.30, but tight-fitting floors shall be provided to support the live and dead loads. (3) Except as provided in Sentences (4) and (5), thermal insulation, vapour barrier, air-barrier construction, interior finishes, plumbing, heating, mechanical ventilation, air-conditioning and electrical facilities, need not be provided, but where any o f these are provided, they shall comply with the requirements of this Part.

(4) Where heating and air-conditioning are provided, Articles 9.33.1.3. need not be complied with.

(5) Where thermal insulation is provided, the minimum thermal resistance of insulation in Table 9.25.2.A. need not be provided.

5. **Applicant's Position**

The Applicants submitted that the building is designed to be, and will be used as a seasonal residential building. As a result, they believe that Subsection 9.36.2. (Cottages) of the Building Code applies. In their view, this Subsection clearly exempts cottages from the heating and ventilation requirements found in other provisions of Part 9. Since they are not intending to use

the building on a year-round basis, they feel that providing additional ventilation would be unnecessary and would add additional costs to their cottage construction.

The Applicants also argue that there does not appear to be a municipal by-law (zoning or otherwise) requiring that new dwellings be designed for permanent residential year-round use. Further, they note that the Respondent initially indicated that this is a Building Code issue and not a zoning issue which the Applicants took to mean that the municipality does not dispute their view that the building can be constructed as a seasonal residential structure on the subject land. If this is the case, then as a cottage building, the exemptions of Subsection 9.36.2. are relevant.

6. **Chief Building Official's Position**

The Respondent submitted that, in their opinion, the subject building was designed, and is being built as a full time residential home. They note that the zoning by-laws for the property in question does not permit seasonal recreational uses. Accordingl y, all applicable provisions of Part 9 of the Building Code are relevant for the construction of the subject building, including Sections 9.25 Thermal Insulation and Control of Condensation, 9.32 Ventilation, 9.33 Heating and Air-Conditioning, and 9.38 Thermal Design.

7. **Commission Ruling**

It is the decision of the Building Code Commission that the residential building provides sufficiency of compliance with 9.32.1.2. of the Building Code.

8. **Reasons**

i) The building is a seasonal recreational use facility. ii) The building is provided with openable windows and with mechanical ventilating fans in washroom facilities.

Dated at Toronto this 15th day in the month of January 1998 for application number 1997-76.

RULING

1. **The Hearing**

   With the consent of the parties, this application was heard together with two other applications involving the Applicant (the other rulings are 97-61-603 and 97-62-604).

   After the first day of the hearing, the Commission requested the Applicant to provide information concerning a time-based egress analysis of the proposed cinema seating design as well as other egress issues. The hearing resumed on February 6, 1998.

2. **The Applicant**

   Mr. Ken Wood, Project Architect, Young and Wright Architects Inc. has applied for a building permit under the *Building Code Act, 1992* to construct a new movie theatre complex containing

30 individual cinema auditoriums at the AMC 30-Plex Movie Theatre Complex, Highways 400 and 407, Vaughan, Ontario.

3. **Description of Construction**

The Applicant proposes to construct a new movie theatre building complex containing 30 individual cinema auditoriums. The structure is described as 2 storeys in building height and is constructed of noncombustible construction. It is equipped with a sprinkler system and fire alarm system. The building is classified as having a Group A - Division 2 major occupancy.

The Applicant is proposing seating and aisle configurations, as well as egress arrangements that vary from traditional seating layouts. Specifically, the Applicant intends to; 1) configure the seating to allow more than 16 seats per row under certain conditions, 2) base the width of the aisles on the total occupant load served, 3) base the width of the means of egress (doors, stairs and ramps) on the total occupant load served and 4) create dead-end aisles serving seating rows that may exceed 6 m in length also under certain conditions. Collectively, this proposed cinema design is known as the "stadium style".

The proposed cinemas vary in size, with occupant loads ranging from approximately 100 to 550. The total occupant load of the building is projected to be roughly 5,000 persons. All seats in the cinemas are to be fixed. The building housing these cinemas conforms with all other provisions of the Ontario Building Code.

4. **Dispute**

The issue at dispute between the Applicant and Respondent is whether the proposed seating and aisle configurations and egress provisions provide sufficiency of compliance with Sentences 3.3.2.3.(2), 3.3.2.4.(2), (3), (4) and (5) of the Ontario Building Code.

Sentence 3.3.2.3.(2) requires that an aisle be located not more than 7 seats away from any seat. Including the two middle seats in a row this means that a row of seats served by an aisle at either end cannot be more than 16 seats. Article 3.3.2.3. also allows a seating configuration known as "continental seating" in which 100 seats are allowed in a row provided there are egress doorways at both ends of the row and that each doorway serves not more than 3 rows of seats. Sentence (4) of Article 3.3.2.3. also provides for alternative forms of seating than the traditional or continental style provided that the standard of safety is not reduced and the egress time is not increased. The Applicant intends to demonstrate that the stadium style of seating, which in some cases contains

more than 16 seats per row, can conform to the Ontario Building Code under Sentence 3.3.2.3.(4).

A second area of dispute is the egress facilities. This issue involves both the requirements for the width of the aisles in the direction of egress travel (Sentence 3.3.2.4.(3)) and of the width of the aisles at their termination point or means of egress, either a cross aisle, foyer or exit (Sentence 3.3.2.4.(4)). Sentence 3.3.2.4.(3) uses the minimum clear width criteria set out for aisles in Sentence 3.3.2.4.(2) and requires that the width be increased by 25 mm for each metre of distance travelled toward the termination point, as measured from the farthest point of the aisle. Sentence 3.3.2.4.(4) stipulates that the means of egress from an aisle, or aisles, be as wide as the widest aisle, plus 50 per cent of the total width of the other aisles served. The proposal put forth is to base both of these widths on the occupant load, with the aisle widths maintaining at least the minimum standards described in 3.3.2.4.(2). (The minimum clear width standards required in Sentence 3.3.2.4.(2) are 1,100 mm, or 750 mm when serving 60 seats or less, and 900 mm when serving seats on one side only.)

Also at issue is the length of dead-end aisles. Sentence 3.3.2.4.(5) states that dead-end aisles cannot be more than 6 m in length. The subject proposal provides four conditions, including increasing the clear width of a row by a formula of 6.1 mm for each seat beyond 16 seats as necessary to travel to an alternative aisle up to a maximum of 550 mm, which if all conditions were met, would allow the dead-end aisle length to be increased.

5. **Provisions of the Ontario Building Code**

Sentence 3.3.2.3.Fixed Seats

(2) Except as provided in Sentence (3), aisles on the main floor and in balconies shall be located so that there are not more than 7 seats between any seat and the nearest aisle.

Sentence 3.3.2.4.Aisles

(2) The minimum clear width of aisles shall be not less than 1 100 mm (3 ft 7 in), except that the width is permitted to be reduced to not less than

(a) 750 mm (2 ft 6 in) when serving not more than 60 seats, and

(b) 900 mm (2 ft 11 in) when serving seats on 1 side only.

(3) Except in the case of bleacher seats, the minimum clear width of aisles referredto in Sentence (2) shall be measured at the point farthest from an exit, cross aisle or foyer and shall be increased in width 25 mm (1 in) for each metre of distance toward the exit, cross aisle or foyer.

(4) Aisles shall terminate in a cross aisle, foyer or exit, and the width of such cross aisle, foyer or exit shall not be less than the required width of the widest aisle plus 50 per cent of the total required width of the remaining aisles that it serves.

(5) Dead end aisles shall be not more than 6 m (19 ft 8 in) in length.

6. **Applicant's Position**

The Applicant submitted that the proposed stadium style cinema design provides sufficiency of compliance with the above cited Ontario Building Code provisions.

Regarding the number of seats in a row served by an aisle at both ends, the Applicant is proposing that limit may exceed 16 provided that; the minimum clear width of the row is 400 mm, that the number of seats in the row does not exceed 100, that the aisles serving the rows do not exceed a dead-end length of 6 m (except as permitted under their proposal to increase dead-end aisles), and that the travel distance from the most remote seat does not exceed 30 m as measured to a doorway or vomitory. The Applicant argued that stadium style seating provides an equivalent level of safety to, and better egress time than continental style seating. They noted that the maximum travel distances to exits in both seating styles is approximately 30 m, but that the doorway widths in the stadium style are slightly larger per person (6.1 mm compared to 6.07 mm). The Applicants also pointed out that the aisle width required in continental seating would result in an exit factor of 7.3 mm per person. Calculating the aisle widths on the basis of total occupant load as is done in the stadium style would result in wider aisles and would therefore achieve a faster flow rate. As well, they note that the occupant flow in stadium style seating would also be faster due to the formula spacing the seats in the rows which allows for a wider row than the 400 mm called for in continental seating.

For these reasons, the Applicant contends that the stadium style seating configuration complies with Sentence 3.3.2.3.(4) and is therefore an equivalent to the continental style of seating as described in Sentence 3.3.2.3.(3) and provides sufficiency of compliance with Sentence 3.3.2.3.(2).

Concerning the egress facilities, the Applicant argues that by basing the widths of aisles and means of egress on the occupant load, more accurate standards are realized than the arbitrary standards found in Sentences 3.3.2.4.(3) and (4). Using 3.3.2.4.(3), for example, which requires an increase in aisle width of 25 mm per metre distance travelled results in both unnecessarily wide aisles in some circumstances, while in other instances, especially large theatres, it produces aisles that are too narrow. The same is true for the width of the means of egress. The Applicant argues that the current Ontario Building Code standards make confusing distinctions between rooms that have fixed seating or not. By setting the requirements at 6.1 mm per person of occupant load a simplified standard emerges based on the true performancedemanded of the means of egress. It is by using this standard that the Applicant argues that some of the smaller cinemas do not require a second exit door.

On the issue of the dead-end aisles, the Applicant is also proposing that their length may exceed 6 m provided that; the minimum clear width of the row is 400 mm, the width of the row is increased by 6.1 mm for each seat beyond 16 seats as necessary to travel to an alternate aisle up to a maximum of 550 mm, and that the travel distance from the most remote seat does not exceed 30 m as measured to an exit doorway. The Applicant argues that these conditions take into consideration if for some reason an aisle becomes inaccessible, the occupants can travel through any row of seats to reach an alternate aisle. For example, these criteria allow for a wider row, if in that row it is necessary to pass more than 7 seats to reach another aisle. As well, using these standards the maximum width of a row could be as much as 550 mm, which would permit occupants to exit in single file.

The Applicant points out that the total travel distance from the most remote seat will not exceed 30 m. In fact, the proposed egress of these dead-end aisles compares favourably with continental seating since, as they contend, the length of travel is the same or better, the rows and aisles would be wider, and there would be a choice to reach alternative doorways to exit the cinema.

In response to the Commission's request, the Applicant also submitted a time-based egress analysis that measured the length of time it would take to exit the proposed cinemas. This study, consistent with the Applicant's entire proposal, was based on a comparison to continental-style seating, which is an Ontario Building Code complying seating configuration. The study examined the three areas (rows, aisles and doorways) that individuals must travel through to reach the egress doorway. The Applicant's analysis showed that it would take 2.48 minutes to exit from a continental-style cinema, with the aisle being the area with the slowest flow time. For the proposed stadium-style seating, which the Applicant is proposing 100 seats in a row

(although the proposals at hand have a maximum of 35 seats per row), the report demonstrated that the egress time, at 2.05 minutes, would be faster than in continental seating. The area of slowest flow time in stadium seating was the doorway. But as the Applicant noted, even the flow time through this door is faster than in the continental style.

7. **Chief Building Official's Position**

The Respondent submitted that the proposed seating configurations in all of the cinemas are not in accordance with the Ontario Building Code. In particular, they note three main areas in which the proposed seating does not comply with the Ontario Building Code. First, the number of seats in a row is, in some cases, up to 29, which exceeds the maximum of 16 set out in Sentence 3.3.2.3.(2). Secondly, the dead end aisles are between 8 and 11 m long, which extends beyond the maximum of 6 m found in Sentence 3.3.2.4.(5). Thirdly, the aisle widths are not increased by 25 mm per metre towards the exit, cross aisle or foyer as per Sentence 3.3.2.4.(3).

The Respondent presented their own time-based egress analysis for small, medium and largecinemas, making a comparison to both conventional Ontario Building Code complying seating and differently configured continental-style seating. (In their view, the Applicant's egress analysis was too simplistic and that the comparison to the continental style, with its 100 seats in a row was unrealistic.) Their analysis demonstrated that the egress time from small, medium and large cinemas with conventional-style seating would be faster than the proposed seating arrangement. In their analysis of the continental style, the Respondent used a model they felt was more realistic. Instead of 100 seats in a row, which they argued no cinema would have, they created (in the large example) a cinema with 22 rows (exactly the same as the Applicant's large cinema example) each having 26 seats. The same re-configuration was done for medium and small cinemas. Their study found that the flow rate and egress time of the modified continental-style seating was significantly lower than the proposed model presented by the Applicant.

For these reasons the Respondent was of the position that the subject proposal, with its occupant load-based approach, provides alternative measures of Ontario Building Code compliance that reach substantially beyond their jurisdiction. In their view, the stadium-style approach to cinema seating design is an entirely new system of egress from a room with fixed seating that is currently not recognized under the Ontario Building Code. It is therefore their position that they do not have the authority to approve these aspects of this project.

8. **Commission Ruling**

It is the decision of the Building Code Commission that the Applicant's proposal has not demonstrated sufficiency of compliance with Sentences 3.3.2.3.(2), 3.3.2.4.(2), 3.3.2.4.(3), 3.3.2.4.(4) and 3.3.2.4.(5) of the Ontario Building Code.

9. **Reasons**

1)Inconsistent evidence was presented by the Applicant and one of the Respondents with respect to exiting times and flow rates.

2)The information provided did not substantiate the basis for sufficiency of compliance. Convincing evidence was not provided that the proposed cinema design would not result in an increase in egress time.

3)No documentation was presented with respect to real life case studies or examples of similarly constructed theatres comparing flow patterns, flow rates, egress times, etc., that may have assisted the Commission members to assess the inconsistencies in the evidence presented.

4)The issue presented is a significant and complex one, it is the opinion of the Building Code Commission that the issue would be better dealt with as an Ontario Building Code amendment.

Dated at Toronto this 17th day in the month of February in the year 1998 for application number 1997-78.

RULING

1. **The Hearing**

   With the consent of the parties, this application was heard together with two other applications involving the Applicant (the other rulings are 97-62-604 and 97-63-605).

   After the first day of the hearing, the Commission requested the Applicant to provide information concerning a time-based egress analysis of the proposed cinema seating design as well as other egress issues. The hearing resumed on February 6, 1998.

2. **The Applicant**

   Mr. Richard Young, Principal, Young and Wright Architects Inc. has applied for a building permit under the *Building Code Act, 1992* to construct a new movie theatre complex containing 24 individual cinema auditoriums at the AMC 24-Plex Movie Theatre, Oakville, Ontario.

3. **Description of Construction**

The Applicant proposes to construct a new movie theatre building complex containing 24 individual cinema auditoriums. The structure is described as 2 storeys in building height and is constructed of noncombustible construction. It is equipped with a sprinkler system and fire alarm system. The building is classified as having a Group A - Division 2 major occupancy.

The Applicant is proposing seating and aisle configurations, as well as egress arrangements that vary from traditional seating layouts. Specifically, the Applicant intends to; 1) configure the seating to allow more than 16 seats per row under certain conditions, 2) base the width of the aisles on the total occupant load served, 3) base the width of the means of egress (doors, stairs and ramps) on the total occupant load served and 4) create dead-end aisles serving seating rows that may exceed 6 m in length also under certain conditions. Collectively, this proposed cinema design is known as the "stadium style".

The proposed cinemas vary in size, with occupant loads ranging from approximately 100 to 550. The total occupant load of the building is projected to be roughly 5,000 persons. All seats in the cinemas are to be fixed. The building housing these cinemas conforms with all other provisions of the Ontario Building Code.

4. **Dispute**

The issue at dispute between the Applicant and Respondent is whether the proposed seatingand aisle configurations and egress provisions provide sufficiency of compliance with Sentences 3.3.2.3.(2), 3.3.2.4.(2), (3), (4) and (5) of the Ontario Building Code.

Sentence 3.3.2.3.(2) requires that an aisle be located not more than 7 seats away from any seat. Including the two middle seats in a row this means that a row of seats served by an aisle at either end cannot be more than 16 seats. Article 3.3.2.3. also allows a seating configuration known as 147;continental seating" in which 100 seats are allowed in a row provided there are egress doorways at both ends of the row and that each doorway serves not more than 3 rows of seats. Sentence (4) of Article 3.3.2.3. also provides for alternative forms of seating than the traditional or continental style provided that the standard of safety is not reduced and the egress time is not increased. The Applicant intends to demonstrate that the stadium style of seating, which in some cases contains more than 16 seats per row, can conform to the Ontario Building Code under Sentence 3.3.2.3.(4).

A second area of dispute is the egress facilities. This issue involves both the requirements for the width of the aisles in the direction of egress travel (Sentence 3.3.2.4.(3)) and of the width of the

aisles at their termination point or means of egress, either a cross aisle, foyer or exit (Sentence 3.3.2.4.(4)). Sentence 3.3.2.4.(3) uses the minimum clear width criteria set out for aisles in Sentence 3.3.2.4.(2) and requires that the width be increased by 25 mm for each metre of distance travelled toward the termination point, as measured from the farthest point of the aisle. Sentence 3.3.2.4.(4) stipulates that the means of egress from an aisle, or aisles, be as wide as the widest aisle, plus 50 per cent of the total width of the other aisles served. The proposal put forth is to base both of these widths on the occupant load, with the aisle widths maintaining at least the minimum standards described in 3.3.2.4.(2). (The minimum clear width standards required in Sentence 3.3.2.4.(2) are 1,100 mm, or 750 mm when serving 60 seats or less, and 900 mm when serving seats on one side only.)

Also at issue is the length of dead-end aisles. Sentence 3.3.2.4.(5) states that dead-end aisles cannot be more than 6 m in length. The subject proposal provides four conditions, including increasing the clear width of a row by a formula of 6.1 mm for each seat beyond 16 seats as necessary to travel to an alternative aisle up to a maximum of 550 mm, which if all conditions were met, would allow the dead-end aisle length to be increased.

5. **Provisions of the Ontario Building Code**

Sentence 3.3.2.3. Fixed Seats

(2) Except as provided in Sentence (3), aisles on the main floor and in balconies shall be located so that there are not more than 7 seats between any seat and the nearest aisle.

Sentence 3.3.2.4.Aisles

(2) The minimum clear width of aisles shall be not less than 1 100 mm (3 ft 7 in), except that the width is permitted to be reduced to not less than

(a) 750 mm (2 ft 6 in) when serving not more than 60 seats, and

(b) 900 mm (2 ft 11 in) when serving seats on 1 side only.

(3) Except in the case of bleacher seats, the minimum clear width of aisles referred to in Sentence (2) shall be measured at the point farthest from an exit, cross aisle or foyer and shall be increased in width 25 mm (1 in) for each metre of distance toward the exit, cross aisle or foyer.

(4) Aisles shall terminate in a cross aisle, foyer or exit, and the width of such cross aisle, foyer or exit shall not be less than the required width of the widest aisle plus 50 per cent of the total required width of the remaining aisles that it serves.

(5) Dead end aisles shall be not more than 6 m (19 ft 8 in) in length.

6. **Applicant's Position**

The Applicant submitted that the proposed stadium style cinema design provides sufficiency of compliance with the above cited Ontario Building Code provisions.

Regarding the number of seats in a row served by an aisle at both ends, the Applicant is proposing that limit may exceed 16 provided that; the minimum clear width of the row is 400 mm, that the number of seats in the row does not exceed 100, that the aisles serving the rows do not exceed a dead-end length of 6 m (except as permitted under their proposal to increase dead-end aisles), and that the travel distance from the most remote seat does not exceed 30 m as measured to a doorway or vomitory. The Applicant argued that stadium style seating provides an equivalent level of safety to, and better egress time than continental style seating. They noted that the maximum travel distances to exits in both seating styles is approximately 30 m, but that the doorway widths in the stadium style are slightly larger per person (6.1 mm compared to 6.07 mm). The Applicants also pointed out that the aisle width required in continental seating would result in an exit factor of 7.3 mm per person. Calculating the aisle widths on the basis of total occupant load as is done in the stadium style would result in wider aisles and would therefore achieve a faster flow rate. As well, they note that the occupant flow in stadium style seating would also be faster due to the formula spacing the seats in the rows which allows for a wider row than the 400 mm called for in continental seating.

For these reasons, the Applicant contends that the stadium style seating configuration complies with Sentence 3.3.2.3.(4) and is therefore an equivalent to the continental style of seating as described in Sentence 3.3.2.3.(3) and provides sufficiency of compliance with Sentence 3.3.2.3.(2).

Concerning the egress facilities, the Applicant argues that by basing the widths of aisles and means of egress on the occupant load, more accurate standards are realized than the arbitrary standards found in Sentences 3.3.2.4.(3) and (4). Using 3.3.2.4.(3), for example, which requires an increase in aisle width of 25 mm per metre distance travelled results in both unnecessarilywide aisles in some circumstances, while in other instances, especially large

theatres, it produces aisles that are too narrow. The same is true for the width of the means of egress. The Applicant argues that the current Ontario Building Code standards make confusing distinctions between rooms that have fixed seating or not. By setting the requirements at 6.1 mm per person of occupant load a simplified standard emerges based on the true performance demanded of the means of egress. It is by using this standard that the Applicant argues that some of the smaller cinemas do not require a second exit door.

On the issue of the dead-end aisles, the Applicant is also proposing that their length may exceed 6 m provided that; the minimum clear width of the row is 400 mm, the width of the row is increased by 6.1 mm for each seat beyond 16 seats as necessary to travel to an alternate aisle up to a maximum of 550 mm, and that the travel distance from the most remote seat does not exceed 30 m as measured to an exit doorway. The Applicant argues that these conditions take into consideration if for some reason an aisle becomes inaccessible, the occupants can travel through any row of seats to reach an alternate aisle. For example, these criteria allow for a wider row, if in that row it is necessary to pass more than 7 seats to reach another aisle. As well, using these standards the maximum width of a row could be as much as 550 mm, which would permit occupants to exit in single file.

The Applicant points out that the total travel distance from the most remote seat will not exceed 30 m. In fact, the proposed egress of these dead-end aisles compares favourably with continental seating since, as they contend, the length of travel is the same or better, the rows and aisles would be wider, and there would be a choice to reach alternative doorways to exit the cinema.

In response to the Commission's request, the Applicant also submitted a time-based egress analysis that measured the length of time it would take to exit the proposed cinemas. This study, consistent with the Applicant's entire proposal, was based on a comparison to continental-style seating, which is an Ontario Building Code complying seating configuration. The study examined the three areas (rows, aisles and doorways) that individuals must travel through to reach the egress doorway. The Applicant's analysis showed that it would take 2.48 minutes to exit from a continental-style cinema, with the aisle being the area with the slowest flow time. For the proposed stadium-style seating, which the Applicant is proposing 100 seats in a row (although the proposals at hand have a maximum of 35 seats per row), the report demonstrated that the egress time, at 2.05 minutes, would be faster than in continental seating. The area of slowest flow time in stadium seating was the doorway. But as the Applicant noted, even the flow time through this door is faster than in the continental style.

7. **Chief Building Official's Position**

The Respondent had two main concerns. The first was the number of seats in a row. They felt that the proposed 100 seats in a row was too many. They wanted the Commission to set down a condition restricting the limit to something far less than 100 seats in a row.

The Respondent's second concern was the proposed travel distance from the most remote seat. They preferred that the travel distance be measured to the egress door leading to the exit and not to a point nearer to the interior of the cinema.

In general, the Respondent submitted that the stadium-style proposal, with its occupant load-based approach, is an entirely new system of egress from a room with fixed seating that is currently not recognized under the Ontario Building Code. It is therefore their position that they do not have the authority to approve these aspects of this project.

8. **Commission Ruling**

It is the decision of the Building Code Commission that the Applicant's proposal has not demonstrated sufficiency of compliance with Sentences 3.3.2.3.(2), 3.3.2.4.(2), 3.3.2.4.(3), 3.3.2.4.(4) and 3.3.2.4.(5) of the Ontario Building Code.

9. **Reasons**

1)Inconsistent evidence was presented by the Applicant and one of the Respondents with respect to exiting times and flow rates.

2)The information provided did not substantiate the basis for sufficiency of compliance. Convincing evidence was not provided that the proposed cinema design would not result in an increase in egress time.

3)No documentation was presented with respect to real life case studies or examples of similarly constructed theatres comparing flow patterns, flow rates, egress times, etc., that may have assisted the Commission members to assess the inconsistencies in the evidence presented.

4)The issue presented is a significant and complex one, it is the opinion of the Building Code Commission that the issue would be better dealt with as an Ontario Building Code amendment.

RULING

1. **The Applicant**

   Mr. Cary Green was issued a building permit under the *Building Code Act, 1992* to renovate an existing commercial building and to construct an addition on the subject structure with the intention of convert the building to residential condominiums at The Orion, 1231 Yonge Street, Toronto, Ontario.

2. **Description of Construction**

   The Applicant proposes to build 37 residential condominiums by renovating and converting an existing three storey commercial building and by constructing a new four storey addition to the subject building. The structure is to be a mixed use building with limited Group D (retail) and Group E (commercial) occupancies proposed for the ground floor. The building is constructed of noncombustible construction and has a building area of approximately 1,911 m2 (19,000 ft 2).

The building is equipped with a fire alarm system, a standpipe and hose system, and a sprinkler system in the basement level only.

The Applicant is proposing to maintain the existing east elevation, currently standing 1.574 m from the property line. The unprotected openings proposed for the east elevation will, however, exceed the allowable limits in Article 3.2.3.1. and Table 3.2.3.A. The proposed increase in unprotected openings ranges from approximately four to eight times the permitted percentage limit. In order to provide protection, the Applicant proposes to install closely spaced sprinklers on all windows and doors on the east elevation to reduce the amount of heat transmitted through the openings.

3. **Dispute**

The issue at dispute between the Applicant and the Respondent is whether the proposed closely spaced sprinklers provide sufficiency of compliance with the allowable maximum openings permitted in Sentence 3.2.3.1.(1) and Table 3.2.3.A. Sentence 3.2.3.1.(1) determines that the area of unprotected opening in an exposing building face shall not exceed the standards found in Table 3.2.3.A. This Table sets out the maximum area of an exposing building face that is permitted to be unprotected openings as a percentage of the entire building face. Table 3.2.3.A. uses a formula for determining the percentage of allowable openings which includes the area of the wall, its ratio of height versus length, and the limiting distance to the nearest property line, or centre of a street, lane or public thoroughfare.

4. **Provisions of the Building Code**

Sentence 3.2.3.1. Limiting Distance and Area of Unprotected Openings

(1) Except as provided in Articles 3.2.3.9. to 3.2.3.11, the area of unprotected openings shall not be more than that set forth in Tables 3.2.3.A. or 3.2.3.B. for the limiting distance applicable to the exposing building face under consideration.

5. **Applicant's Position**

The Applicant submitted that the proposed installation of closely spaced sprinklers at all windows and doors on the east elevation provides sufficiency of compliance with Sentence 3.2.3.1.(1). They argue that the water curtain provided by this sprinkler system has proven effective at controlling the spread of fire through openings. Three separate testing agencies (the

British Joint Fire Research Organization, the National Fire Prevention Association, and the National Research Council of Canada) were cited and their research regarding closely spaced sprinklers as a system to protect openings was discussed. Based on this independent analysis, and installation according to the NFPA-13 standards, the Applicant believes that such a sprinkler system would adequately protect the openings.

The Applicant argues that the tests show that the water curtain provided by closely spaced sprinklers significantly reduces the incident radiation passing through the opening. In fact, some tests demonstrated that the sprinkler system prevented combustible material located 3 m from the test opening from igniting. As the Applicant also noted, at this distance, any theoretical building constructed only 3 m away (or 1.426 m from the property line on the adjacent property) would be required to constructed of noncombustible construction, thus further eliminating any chance that a fire may spread from one building to the other.

The Applicant also notes that the adjacent property abutting the subject east elevation is a public transit (subway) right-of-way roughly 39 m wide, the surface of which is designated by municipal by-law as common outdoor space and is being used by another neighbouring property owner to satisfy their municipal zoning requirements for landscaped open space. In fact, the municipality is currently discussing the idea designating the area as a public park. As such, the construction potential of this outdoor space is severely limited, which means that the proposed increase in unprotected openings would have little impact on an adjacent structure since it appears likely that no building would ever be erected.

6. **Chief Building Official's Position**

The Respondent submitted that the proposed window areas on the east exposing face will greatly exceed the maximum permitted openings in the OBC. They argue that the proposed closely spaced sprinklers do not provide sufficiency of compliance with Sentence 3.2.3.1.(1) of the Code. In their opinion, the OBC does not recognize this form of protection because this system of closely spaced sprinklers has not been evaluated nor tested by an accredited testing agency. They argue that the research regarding closely spaced sprinklers referenced by the Applicant is inconclusive and perhaps may not fit the present situation exactly from a testing point of view. As a result, it is their position that the unprotected openings should be designed and built to comply with the Ontario Building Code.

The municipality also recognizes the situation regarding the abutting property. They admit that while construction potential is limited, the Code does not recognize public transit right-of-ways,

nor municipally designated outdoor spaces for the purposes of determining limiting distances. As a result, they recommend that the Applicant reach a covenant with the adjacent owner to limit future construction on the neighbouring property.

7. **Commission Ruling**

It is the decision of the Building Code Commission that the proposed closely spaced sprinkler system designed to protect the window openings does not provide sufficiency of compliance with Sentence 3.2.3.1.(1) and Table 3.2.3.A.

8. **Reasons**

1) No evidence was provided that this specific sprinkler system has been tested for the proposed exterior wall assembly by a recognized testing agency.

2) Other Code complying options are available to the Applicant to provide protection to these enlarged unprotected openings.

Dated at Toronto this 18th day in the month of December in the year 1997 for application number 1997-69.

BCC Ruling No. 97-59-601

BUILDING CODE COMMISSION DECISION ON B.C.C. #97-59-601

IN THE MATTER OF Subsection 24 (1) of the *Building Code Act, 1992*.

AND IN THE MATTER OF Subsection 9.10.19. and Sentence 3.2.5.8.(2) of "the Ontario Building Code" (Ontario Regulation 419/89 as amended by Ont. Reg. 183/88, 581/88, 11/89 and 115/89).

AND IN THE MATTER OF an application by Mr. Rick McConnell, Director, Engineering, Tribunal Developments Inc., 23 Lesmill Road, Ste. 401, North York, Ontario, for the resolution of a dispute with Mr. Jack Tupling, Director of Public Works, Town of Orangeville, Ontario, to determine whether the proposed fire hydrant spacing in relation to the distance to the rear lane garages provides sufficiency of compliance with Subsection 9.10.19 and Sentence 3.2.5.8.(2) of the Ontario Building Code at Montgomery Village, Phases 2 and 3, Orangeville, Ontario.

RULING

1. **The Applicant**

   Mr. Rick McConnell, Tribunal Developments Inc., applied for a building permit under the *Building Code Act, 1992* for Montgomery Village 1, Phases 2 and 3, a residential subdivision in Orangeville, Ontario.

2. **Description of Construction**

   Montgomery Village comprises a combination of single-detached dwellings and row houses. Each dwelling may have a detached frame garage abutting the rear lane. The access to the garage is from the rear lane. Side yard set-backs in the zoning by-law allow a minimum separation of 1.8 metres between dwellings. Montgomery Village, Phase I, was the first subdivision of this configuration (public streets and rear lanes) in the Town of Orangeville and the Town developed servicing standards in Phase I which were applied to Phases 2 and 3. The servicing standards

developed for Phase I and implemented by the Applicant included the provision of fire hydrants in the rear public lanes.

3. **Dispute**

The dispute between the Applicant and Respondent is whether fire hydrants are required on both a main street and rear lane in a residential development having a detached garage at the rear of the lots to provide compliance with the Ontario Building Code.

4. **Provisions of the Ontario Building Code**

Subsection 9.10.19.3. Fire Department Access to Buildings

(1) Access for fire department equipment shall be provided to each building by means of a street, provided to each building by means of a street, private roadway or yard.

(2) Where access to a building as required in Sentence (1) is provided by means of a roadway or yard, the design and location of such roadway or yard shall take into account connection with public thoroughfares, weight of fire fighting equipment, width of roadway, radius of curves, overhead clearance, location of fire hydrants, location of fire department connections and vehicular parking.

Sentence 3.2.5.8. Water Supply

(2) Hydrants shall be located within 90 m (295 ft 3 in) horizontally of any portion of a building perimeter which is required to face a street in Subsection 3.2.2.

5. **Applicant's Position**

The Applicant's position is that there are no requirements in Part 9 of the Ontario Building Code for placement of fire hydrants. Sentence 3.2.5.8.(2) of the Ontario Building Code requires a fire hydrant to be located within 90 metres of the building perimeter which is required to face a street. For Part 9 buildings, only the front of the houses is required to face a street for fire department access. Fire hydrants are proposed to be provided so that they are within 90 metre of the front of each house.

The houses in Montgomery Village are provided with detached garages which are located at the rear of the residential lot and are accessed from a rear lane. It is the Applicant's position that the

garages are considered to be part of the same building as a house since it waives the requirements for spatial separation between these two elements in Sentence 9.10.14.14.(4) of the OBC. The Applicant's opinion is that the provision of a fire hydrant within 90 m of the front of the house meets the intent of Sentence 3.2.5.8.(2) of the Ontario Building Code. This would necessitate the fire department pulling hose between houses to reach a garage fire. The Respondent's opinion is that the Municipal By-law of Orangeville requires fire hydrants within 100 m of the garage. However, it should be noted that the By-law only requires water mains to be provided to each lot or block and does not require water mains to be provided to both sides of a lot.

6. **Chief Building Official's Position**

The Respondent took the position that there was no dispute between the Respondent's Chief Building Official and the Applicant concerning the application to the subject property of the Ontario Building Code.

The Director of Public Works for the Town of Orangeville has requested additional fire hydrants in 3 locations in the rear lane. The Public Works Department is of the opinion that access between houses to the detached garages is inadequate for fire fighting purposes and may be obstructed by fences, snow and other material. Therefore fire fighting equipment should be brought in through the rear lanes. In consultation with the Fire Department, the Public Works Department has established the requirements for the location of fire hydrants.

The dispute concerns the standard for municipal services and public streets in a subdivision and does not concern a "building" within the meaning of the *Building Code Act, 1992*.

Municipal water mains and hydrants in public streets and laneways are not "plumbing" within the meaning of the *Building Code Act, 1992*. The installation of municipal water mains and hydrants is regulated under the *Ontario Water Resources Act*, and the Applicant has sought and obtained approval under that Act.

The Respondent submits that, in any event, the Applicant's reference to Sentence 3.2.5.8.(2) of the Ontario Building Code is inappropriate. The buildings under dispute are governed by Part 9 and not Part 3 of the Ontario Building Code.

Finally, there is no basis for concluding that because Section 9.10.14.14.(4) of the Ontario Building Code waives the requirement for limiting distance between a detached garage and the

dwelling unit where both are located on the same property, a detached garage is not to be considered a separate "building" within the meaning of the *Building Code Act, 1992*. The term "building" is defined Section 1 of the Act and not in the Ontario Building Code, which is a regulation. The definition of "building" under the Act clearly includes a detached garage.

7. **Commission Ruling**

It is the decision of the Building Code Commission that under s. 24(1) of the *Building Code Act, 1992*, the Building Code Commission does not have the jurisdiction to determine this dispute.

8. **Reasons**

1) Under s. 24(1) of the *Building Code Act, 1992*, the Building Code Commission has jurisdiction to resolve disputes:

- that are between a chief building official or building inspector and an applicant for, or holder of, a permit or a person to whom an order is given; and

- that concern the interpretation of, or the sufficiency of compliance with, the technical requirements of the Ontario Building Code.

While there appears to be a dispute between the Applicant and the municipality in respect of the fire hydrant spacing, this dispute is not with the municipality's Chief Building Official or building inspector, and it does not relate to the interpretation of, or sufficiency of compliance with, the technical requirements of the Ontario Building Code.

2) The dispute arises on property which is not part of the subject property of the buildings in question. Evidence was provided that the rear laneway in question is a dedicated street.

RULING

1. **The Applicant**

   Ms. Elizabeth Sawicki, NHD Developments Ltd. was issued a building permit under the *Building Code Act, 1992* to construct Concord Confections, at 345 Courtland Avenue, Vaughan, Ontario.

2. **Description of Construction**

   The structure is a single-storey industrial building with a building area of 12,156 square metres, of non-combustible construction with a sprinkler system and fire alarm. Article 3.2.2.54 of the Ontario Building Code requires the building to face one street and to be constructed of non-combustible materials and mezzanines having a 1 hour fire resistance rating. The roof rating is waived since the building is protected with an electronically supervised sprinkler system.

The north wall which is 100 m, is provided with 3 doors and a wall of glass 43 m wide. The building site is provided with one fire hydrant at the north east corner of the building. As part of the City of Vaughan's plan review, an additional fire hydrant was required at the north west corner of the site. The City requires the entire north elevation to have access openings within 3-15 metres of the street in order to be accessible for fire route requirements under Articles 3.2.5.6 and 3.2.5.7 of the Building Code. Forty-five per cent of the building perimeter is within 3-15 metres of a fire department access route.

3. **Dispute**

The dispute between the Applicant and Respondent is whether an additional fire hydrant is to be installed at the north west corner of the site to comply with Sentence 3.2.5.8.(2) of the Ontario Building Code.

4. **Provisions of the Building Code**

3.2.5.8. Water Supply

(2) Hydrants shall be located within 90 m (295 ft 3 in) horizontally of any portion of a building required to face a street in Subsection 3.2.2.

5. **Applicant's Position**

The Applicant considers that the proposed building configuration as submitted to the City of Vaughan be considered as providing sufficiency of compliance with the requirements of the City of Vaughan. Since a significant portion of the north and east elevation of the building is within 15 m of a street (45% of the entire building perimeter), it can be considered as facing one street for purposes of fire department access.

The access openings are waived for sprinklered buildings under Article 3.2.5.3 of the Building Code. However, Concord Confections which is sprinklered, does have 3 doors on the north wall.

6. **Chief Building Official's Position**

The building faces one street with its principal entrance facing the required fire route. An additional hydrant is required at the end of the fire route or the existing private hydrant could be relocated so as to be within 90 m of the end of the building to comply with Sentence 3.2.5.8.(2).

7. **Commission Ruling**

It is the decision of the Building Code Commission that the proposed building faces one street and provides sufficiency of compliance with Sentence 3.2.5.8.(2) of the Building Code.

Conditions:

i) The existing paved road on the east side of the building be designated as a fire route, including the required turn-around at the south end.

ii) Any proposed additions as noted on the plans must comply with Code requirements.

8. **Reasons**

a) The principal entrance is located within 90 m of the hydrant.

b) The building is fully sprinklered, and therefore does not require any additional access openings.

c) The paved area along part of the east side complies with the requirements for an access route.

RULING

1. **The Applicant**

   Mr. Robert DeGasperis is an individual to whom a building permit was issued under the *Building Code Act, 1992* to construct two warehouses for the storage of aerosol products or combustible and noncombustible paint products at the Sherwin-Williams Facility, 200 Confederation Parkway, Vaughan, Ontario.

2. **Description of Construction**

   The Applicant is proposing to construct a Group F - Division 1 (high hazard industrial occupancy) storage facility. The building is described as a single storey warehouse with a building area of 9,475 m2 (102,000 ft2). It is proposed to erect a firewall in the middle to divide the building into two smaller buildings. The buildings on either side of this firewall are to be

constructed of noncombustible construction. Both buildings will be equipped with a fire alarm system, a standpipe and hose system, and a automatic sprinkler system.

The Applicant is proposing to construct this facility with a maximum travel distance to the exits of 38 m. This represents an increase of 10 m over the allowable maximum set out in the Building Code for this type of structure. To compensate for this additional travel distance, the Applicant is proposing to install an early suppression fast response (ESFR) sprinkler system, instead of the standard sprinkler system required by the Code.

3. **Dispute**

The issue at dispute between the Applicant and Respondent is whether the proposed installation of an ESFR sprinkler system in lieu of standard sprinklers provides sufficiency of compliance with Clause 3.4.2.5.(1)(a) of the Ontario Building Code. This provision requires that the maximum travel distance to an exit be not more than 25 m in a high hazard industrial occupancy. As noted, the Applicant's are proposing a maximum travel distance of 35 m in the subject warehouse.

4. **Provisions of the Building Code**

3.4.2.5. Location of Exits

(1) Except as provided in Sentence (2),(3) and 3.3.2.4.(6), where more than one exit is required from a floor area, such exits shall be located so that the travel distance to not less than one exit as described in Article 3.4.2.4. shall be not more than

(a) 25 m (82 ft) in any Group F, Division 1 occupancy,

5. **Applicant's Position**

The Applicant submitted that the installation of early suppression fast response sprinkler system provides sufficiency of compliance with Clause 3.4.2.5.(1)(a) of the Code. In their view, the upgraded sprinkler system would actuate quicker and would therefore allow occupants additional time to evacuate the building. The Applicant provided calculations indicating that the response time index (RTI) of a standard sprinkler system is 400. This translates into an actuation time of 4.5 minutes. The proposed ESFR sprinklers however have an RTI of 50, which equals an actuation time of .5 minutes. This earlier warning (of four minutes) would more than adequately allow the occupants enough time to travel the additional 10 m to the exits in the event of an

emergency. In fact, the Applicant argues that with an ESFR system, the travel distance to the exit could 304 m farther while still maintaining the same level of safety as is required under the Code.

The Applicant also notes that the proposed occupant load in the facility is only 20 people which would mean very little crowding at exits. As well, the exit capacity far exceeds that which is required for the occupant load. The occupants of the warehouse would all be working on EE classified forklifts, which as the Applicant suggests, would mean that travel to the exits may be by forklift rather than on foot. Finally, it was noted that the ultraviolet detection system would provide quick identification of any fire.

6. **Chief Building Official's Position**

The Respondent submitted that the proposed travel distances do not meet the requirements of Clause 3.4.2.5.(1)(a) of the OBC. The maximum allowable travel distance for an F1 building is not to exceed 25 m. They argue that the Applicant has increased the travel distance so that the facility may accommodate additional rack storage.

7. **Commission Ruling**

It is the decision of the Building Code Commission that a travel distance of 38 m does not provide sufficiency of compliance with Clause 3.4.2.5.(1).

8. **Reasons**

i) The Code does not distinguish between ESFR and regular sprinklers.

ii) The municipality has agreed to allow up to a 5 m additional travel distance (30m in total) in recognition of the increased performance provided by the ESFR sprinklers. iii) The in-rack sprinklering proposed by the Applicant is already a Code requirement.

Dated at Toronto this 11th day in the month of December in the year 1997 for application number 1997-66.

The Respondent

RULING

1. **The Applicant**

   Mr. Duncan McGill was issued a building permit under the *Building Code Act, 1992* to undertake renovations at Joseph Brant Memorial Hospital, 1230 Northshore Boulevard East in Burlington, Ontario.

2. **Description of Construction**

   Joseph Brant Memorial Hospital is a 6 storey building that is partially sprinklered (30%). It is being renovated for long term care including addition of sprinklers as areas are renovated. The 4th floor which is the subject of dispute is presently sprinklered.

3. **Dispute**

The dispute concerns renovations to the south and east wings of the 4th floor and whether self-closing devices are required between the corridors and sleeping rooms in accordance with Sentence 3.1.8.11. (5). of the Ontario Building Code.

4. **Provisions of the Building Code**

3.1.8.11. Self-Closing Devices

(5) Self-Closing devices need not be provided on doors that are located between sleeping rooms or a corridor and adjacent sleeping rooms where the doors are within a fire-compartment described in Sentence 3.3.3.7.(2).

3.3.3.7. Sprinklered Hospitals and Nursing Homes

(2) Except as provided in Sentence (3), floor areas containing patients' sleeping rooms in hospitals and nursing homes shall be divided into not less than 2 fire compartments not more than 1,000 m2 (10,800 ft2) in area.

5. **Applicant's Position**

The Applicant seeks Code exemption for suite door closers under Sentence 3.1.8.11.(5) of the Ontario Building Code. The Applicant interprets the exemption for floor areas divided into not less than 2 fire compartments not more than 1000 square metres in area. This project has been designed with three individual fire compartments of 728,500 and 536 square metres each, with 1-hour fire resistance rated separations between compartments, meeting the requirements of Sentence 3.1.8.11.(5). The exemption is not conditional on sprinklers, however , the project is sprinklered, in conformance with NFPA Standards as designed by the mechanical consultant.

6. **Chief Building Official's Position**

The Respondent's position is that the exemption for self-closing devices only applies to areas described under Sentence 3.3.3.7(2) of the Code which is for fully sprinklered buildings only. The building is only 30% sprinklered.

7. **Commission Ruling**

It is the decision of the Building Code Commission that not providing self-closing devices on fourth floor sleeping room doors provides sufficiency of compliance with Sentence 3.1.8.11.(5)

of the Building Code provided that the entire fourth floor is fully sprinklered within 90 days from January 1, 1998.

8. **Reasons**

i) The level of safety intended by Sentences 3.1.8.11.(5) and 3.3.3.7.(2) will be provided.

RULING

1. **The Applicant**

   Mr. Paul Heleno is a person who was issued a building permit under the *Building Code Act, 1992* to construct a 15 storey residential tower with a mercantile occupancy on the ground floor known as the Residences at Bamburgh Gate, at 1883 McNicholl Avenue, Scarborough,Ontario.

2. **Description of Construction**

   The Applicant proposes to construct a residential condominium tower 15 storeys in building height. The building is constructed of noncombustible construction. It is equipped with a fire alarm system, a voice communication system, a standpipe and hose system, as well as a partial sprinkler system. The structure has a building area of approximately 2,760 m2. The building is classified as having a Group C - residential major occupancy. A certain amount of space on the ground floor has been designated as retail, or Group E - mercantile occupancy.

The Applicant's design for the Suites 1B located on floors 2 through 11 between Grid Lines 11 and 16 creates a travel distance for that unit of 31.82 m as measured from the suite door frame to the exit door frame. (The corridors serving the residential suites of the subject building are separated from the adjacent floor areas by rated fire separations. Therefore, the travel distance may be measured from the entrance doors of the suites.) This exceeds the allowed maximum of 30 m as set out in the OBC. All other suites meet the travel distance requirements.

The firewalls originally proposed that would have allowed the Suites 1B to be in full conformance with the 30 m travel distance requirement were deleted. Instead, the Applicant is intending to provide additional measures to compensate for the excess travel distance. Specifically, these measures include the installation of additional smoke detectors in the corridors in the vicinity of the Suites 1B and providing pressurization in all exit shafts.

3. **Dispute**

The issue at dispute between the Applicant and the Respondent is whether the proposed measures provide sufficiency of compliance with Clause 3.4.2.5.(1)(f) of the OBC. This provision stipulates that the travel distance to an exit on a floor in this type of occupancy must be 30 m or less.

4. **Provisions of the Building Code**

3.4.2.5.(1)(f) Location of Exits

(1) Except as provided in Sentences (2), (3) and 3.3.2.4.(6), where more than one exit is required from a floor area, such exits shall be located so that the travel distance to not less than one exit as described in Article 3.4.2.4. shall be not more than (f) 30 m (98 ft 5 in) in any other occupancy.

5. **Applicant's Position** The Applicant submitted that these two additional measures provide sufficiency of compliance for the additional travel distance involved regarding the Suites 1B. As the Applicant notes, the Code requires that only the fire fighter's elevator be pressurized in this type of occupancy, and yet they have provide complete pressurization for all exits. This measure goes beyond the mandatory standards in the OBC, they argue.

The additional smoke detectors, as noted, will be located in the public corridors in the vicinity of the Suites 1B. In the event of a fire, these detectors will provide additional early warning to the occupants in the Suites 1B.

Lastly, the Applicant points out that the travel distance issue involves only one suite per floor and given the addition of improved smoke control measures and earlier warning through the pressurization of exits and installation of more smoke detectors, the actual travel distance of 31.82 m should be viewed as equivalent to the requirements of the OBC.

6. **Chief Building Official's Position**

The Respondent submitted that the proposed measures do not provide sufficiency of compliance with Clause 3.4.2.5.(1)(f). In their view, the deletion of the original firewall in the corridor has increased the travel distance and the time required to exit. They believe that additional smoke detectors do not provide equivalent protection.

7. **Commission Ruling**

It is the decision of the Building Code Commission that the distance of travel from suite (1B) provides sufficiency of compliance with Clause 3.4.2.5.(1)(f) of the Building Code provided that

i) the grade stairwells are pressurized to limit smoke movement in accordance with measure G of the supplement to the National Building Code where they connect to the building from above and below grade.

ii) two additional smoke detectors are provided on all typical residential floors in the location of the suite not within the travel distance requirements.

iii) the fresh air supply fans are activated by the fire alarm system and powered by a secondary power source.

8. **Reasons**

i) the distance of travel to from the Suite 1B to the exit from the floor level affects only one suite per floor on floors 2 to 11 and exceeds the requirements by only a minimum 6% or 1.82 m.

ii) the additional detection provides increased early warning in a fire conditions.

iii) the pressurization of the stairwells and corridors should allow the occupants more time to evacuate the building.

iv) it is the opinion of the Building Code Commission that these additional measures compensate for the minimal additional egress travel distance of 1.82 m from Suite 1B on floors (2 - 11).

Dated at Toronto this 26th day in the month of November in the year 1997 for application number 1997-67.

RULING

1. **The Applicant**

   Mr. Dennis Meret, Vice President, Village Grove (1995) Inc., 181-13300 Tecumseh Road East, Tecumseh, Ontario was issued a building permit under the *Building Code Act, 1992* to construct 17 new low rise residential townhouse condominium at 309-395 Jason Court, Village of St. Clair Beach, Ontario.

2. **Description of Construction**

   The Applicant proposes to construct 17 one storey, two bedroom, townhouse condominiums, as part of a larger residential condominium project. The 17 units are grouped into three buildings, two containing six units and the other with five units. The aggregate size of the buildings, approximately 995 m2, meant they were constructed according to Part 3 of the Building Code.

The buildings are classified as Group C - residential. They are constructed of combustible construction.

As the subject units are a single storey, only two steps are required at the front entrance door. The Applicant proposes to not provide handrails for these stairs. This would be consistent with other buildings in this project that were constructed under Part 9, and were not required to provide handrails.

3. **Dispute**

The issue at dispute between the Applicant and the Respondent is whether the proposed front door steps are exit stairs and should be required to provide handrails under Article 3.4.6.4. of the OBC. Article 3.4.6.4. sets out the requirements for handrails.

It states that every exit ramp or stairway must have a handrail.

4. Provisions of the Building Code

3.4.6.4. Handrails

(1) Every exit ramp or stairway shall have a handrail on atleast one side, and where 1 100 mm (3 ft 7 in) or more in width, shall have handrails on both sides.

5. **Applicant's Position**

The Applicant submitted that the proposed exiting stairs, without a handrail, meets the intent of the Code. It is their interpretation that the subject front door steps are not designated as exit stairs under the OBC and therefore handrails are required. They note that the units in question are only required to provide handrails since the size of the buildings made it necessary to build under Part 3. As a comparison, they point to other townhouses (the north side of Jason Court) also constructed at this site which were built to the standards under Part 9. Despite the fact that the north side units contain three bedrooms, meaning potentially more occupants per unit, and also have only two stairs at the front door, they are not required to have handrails.

In their view, Part 3 of the Building Code is intended for areas used extensively by the general public. Since these are private residential townhouses, the Applicant argues that the Part 3 handrail requirement is not necessary.

Further, they note that from a practical standpoint the subject stairs only contain two steps. The total height, including the step from the landing to grade-level of the unit, is well below the 600 mm height difference allowed under Part 9 of the Code before a railing is required.

6. **Chief Building Official's Position**

The Respondent submitted that the subject exit lacks the required handrails and thus does not meet Article 3.4.6.4. of the Code. In their interpretation, the landing and stairs serving these exit doors should be regarded as exit stairs since they provide a means of egress from the floor area they serve. They feel that the subject stairs are used by the public, as well as the unit's occupants. As a result, they conclude that the full Part 3 standards should apply. This includes the requirements for handrails as well as guards.

The Respondent notes that they do not have the authority to waive or vary from the requirements of the OBC.

7. **Commission Ruling**

It is the decision of the Building Code Commission that front door steps which are part of the exit serving each dwelling unit provide sufficiency of compliance with Articles 3.4.6.4., of the Building Code provided they satisfy the requirements of sentences 9.8.7.1.(2) and 9.8.8.1.(1) of the Building Code.

8. **Reasons**

i) It is the opinion of the Building Code Commission that although the building area requires the building to comply with Part 3 of the Building Code, the degree of safety achieved through Part 9 building requirements for handrails and guards would not be reduced in this application.

ii) Each dwelling unit has it's own exit and does not share individual stairs, or steps.

iii) The difference in elevation between the landing and grade is less than 20".

Dated at Toronto this 13th day in the month of November in the year 1997 for application number 1997-60.

RULING

1. **The Applicant**

   Mr. Richard Laplante, President, Builder's Warehouse, Orleans, Ontario is a person to whom a building permit was issued under the Building Code Act, 1992 to construct a new, self-serve warehouse and kiosk, at 3636 Innes Road, Orleans, Ontario.

2. **Description of Construction**

   The Applicant recently constructed a Self-Serve Warehouse and Kiosk facility. The structure is intended for use as a public warehouse building in which individuals store belongings on multi-level racks.

   The building is described as 1 storey in building height and 4076 m2 in roof area, and constructed of noncombustible construction. The structure is classified as having Group F, Division 2 major occupancy. It is equipped with a standpipe and hose system. The pressure in the

standpipe and hose system is, however, 62 kPa (9psi) lower than the 450 kPa (65.3 psi) required under the OBC.

To compensate, the Applicant is proposing to provide an additional fire hydrant adjacent to the building, as well as supplying extra fire extinguishers within the structure.

3. **Dispute**

The issue at dispute between the Applicant and Respondent is whether the proposed measures will provide sufficiency of compliance with Article 3.2.9.3. of the Ontario Building Code. In particular, will the addition of an extra hydrant and fire extinguishers be adequate to compensate for the approximately 14% pressure deficiency in the standpipe and hose system. Sentence 3.2.9.3.(6) of the OBC allows the residual water pressure at the design flow rate at the topmost outlet of a standpipe and hose system to be less than 450 kPa (65.3 psi) if certain conditions, such as sprinklering the building, are met. Since the subject building is not equipped with a sprinkler system, it does not meet these conditions.

4. **Provisions of the Building Code**

Sentence 3.2.9.3.(6) Standpipe and Hose System Design

(6) The residual water pressure at the design flow rate at the topmost outlet of a standpipe and hose system that is required to be installed in a building is permitted to be less than 450 kPa (65.3 psi) provided that

(a) the building is sprinklered in conformance the requirements of Sentence 3.2.5.13.(1), (b) the water supply at the base of the sprinkler riser is capable of meeting the design flow rate and pressure demand of the sprinkler system, including the inside and outside hose allowance, and (c) fire protection equipment is available to deliver, by means of the fire department connection, the full demand flow rate at a residual water pressure of 450 kPa (65.3 psi) at the topmost outlet of the standpipe and hose system.

5. **Applicant's Position**

The Applicant submitted that the proposed measures provide sufficiency of compliance with Article 3.2.9.3. of the OBC. In their view, the addition of an extra fire hydrant and fire extinguishers should be considered as adequate compensation for the 62 kPa (9 psi) shortfall in the standpipe and hose system's pressure.

The note that the Respondent is prepared to accept this alternative.

6. Chief Building Official's Position

The Respondent submitted that the structure, as recently built, does not conform with the requirements of the OBC. It is their opinion that the proposed measures do not comply with the Code, nor can they be considered as equivalents under Section 2.7. The municipality's fire department has indicated that they have no concerns with the Applicant's measures provided that the proposed hydrant is located north-west of the entry kiosk. The fire department believes that by placing the hydrant at this location this would assist them in fire fighting.

The Respondent notes that while they support this proposal, they do not have the authority to approve it.

7. Commission Ruling

It is the decision of the Building Code Commission that building A 3636 Innis Road provides sufficiency of compliance with 3.2.9.3.(6) of the Building Code provided an additional fire hydrant is located on the property to the North West of the entry Kiosk outside the fenced enclosure.

8. **Reasons**

i) The building open on all four sides is one storey in height and access for fire fighting is available from the exterior. ii) The additional hydrant provides additional water supply on the site for internal and external fire fighting purposes. iii) The location of the hydrant is consistent with the pre fire planning needs established by the fire department. iv) A fire department connection is provided to permit the fire department to pressurize the standpipe system from the hydrant on the property.

RULING

1. **The Applicant**

   Mr. Scott Paris, President, Rosemount Development Ltd., 125 Norfinch Drive, Downsview, Ontario was recently issued a building permit under the Building Code Act, 1992 to construct 42 new residential townhouses at Weston Mews, 50 Church Street, City of York, Ontario.

2. **Description of Construction**

The Applicant proposes to construct 42 townhouses, grouped into five buildings. The five buildings range in building area from 332 m2 (building no. 4) to 421 m2 (building no. 3). As such, all buildings were built according to Part 9 of the Building Code. The project consists of five different unit types, all of which are three storeys in building height plus a basement level. The units are generally long and narrow, ranging in width from 4.1 m (A and B units) to 6 m (E units). The buildings are constructed of noncombustible construction.

The Applicant constructed the stairs in many units between the ground floor and basement level so that the guard separating the ground floor from the basement stairs projects vertically from the wall within the stair well. The result of this arrangement is that width of the stair has been reduced by the presence of the vertical pickets the top rail of the guard. The stair widths vary between units, but the narrowest identified was 838 mm (2 ft 9 1/8 in).

Further, the Applicant has constructed the stairs in unit types A and B between the ground and second floors with the stringer of the above stairs protruding up to 190 mm (7 1/2 in) into the headroom of the ground to second floor stairs. The obstruction occurs over the convergence point of the winders of the subject stairs.

3. **Dispute**

The issues at dispute between the Applicant and Respondent are whether the stairs, as constructed, provide sufficiency of compliance with Sentence 9.8.3.3.(2) regarding minimum stair width and whether Article 9.8.3.4. requires that the minimum headroom for stairs in a dwelling unit stipulated in the Building Code must be provided for the full width of the stair tread. Sentence 9.8.3.3.(2) states that at least one stair way between floor levels in a dwelling unit shall have a minimum width between wall faces of not less than 860 mm (2 ft 10 in). The stairs of many of the units, measured at 838 mm (2 ft 9 1/8 in), are 22 mm (7/8 in) less than the required minimum width. Article 9.8.3.4. requires that the headroom for stairs in a dwelling unit shall be 1,950 mm (6 ft 5 in) measured vertically from a line drawn through the outer edges of the nosings. Due to the 190 mm (7 1/2 in) headroom obstruction at the convergence point of the winders in certain stairs in the A and B units, the required headroom is not provided over the full width of the stairs.

4. **Provisions of the Building Code**

Sentence 9.8.3.3. Stair Width

(2) At least 1 stairway between each floor level in a dwelling unit shall have a minimum width between wall faces of not less than 860 mm (2 ft 10 in).

Article 9.8.3.4. Headroom. The headroom measured vertically from a line drawn through the outer edges of the nosing shall be at least 1.95 m (6 ft 5 in) for stairs located in dwelling units and 2.05 m (6 ft 9 in) for all other stairs.

5. **Applicant's Position**

The Applicant submitted that regarding the stair width issue, the stairs, as constructed, provide sufficiency of compliance with Sentence 9.8.3.3.(2). They argue that the landing between the ground floor and the basement level is, on average, 920 mm by 1,020 mm where only 860 mm by 860 mm is required under Article 9.8.4.1. Following this argument, the Applicant also notes that the hallway on the ground floor is, on average, 840 mm in width whereas the requirement under OBC 9.5.8.1. allows for hallways as narrow as 710 mm (2 ft 4 in) in dwellings not exceeding 4.3 m (14 ft 1 in). They believe that this additional space on the landing and in the ground floor hall compensates for the 22 mm deficiency in the width of some of the stairs.

Concerning the issue of the stair headroom, the Applicant believes that the stairs, as constructed, meet the intention of Article 9.8.3.4. They note that this provision does not state that the minimum height must be provided for the entire width of the stair tread. As they note, the obstruction in question occurs over the convergence point of the winders where the steps will not likely be used.

6. **Chief Building Official's Position**

The Respondent submitted that the subject stairs do not provide sufficiency of compliance with Sentence 9.8.3.3.(2) due to the vertical pickets and top rail of the guardrail which reduce the stair width. They do not share the Applicant's view that the wider landing and ground floor hall mitigate the stair width deficiency. In their view, Article 9.5.8.1. is not applicable because it deals with hallway widths and the situation at hand is a stairway.

The Respondent's opinion on the headroom dispute is that Article 9.8.3.4. requires a minimum headroom for the full width of the stair tread. In their interpretation of this provision the obstruction below the stringer and above the convergence point of the winders does not comply with OBC 9.8.3.4. They believe the width is measured between wall faces and/or guards. Using this measurement, the headroom is 190 mm (7 1/2 in) less than that required. To illustrate their

point, they reference the Guide and Illustrations - Part of the Ontario Building Code (Page 29)which states that "headroom over winders must be measured over the narrow portion of the stair to ensure compliance with minimum headroom clearances."

7. **Commission Ruling**

It is the decision of the Building Code Commission that the clearance between the wall face and the guard provides sufficiency of compliance with Sentence 9.8.3.3.(2) of the Building Code,

AND

the headroom measured vertically at the outside edge of the stringer at 1765 mm provides sufficiency of compliance with Article 9.8.3.4. of the Building Code.

8. **Reasons**

i) The guard obstruction is minimal as a result of the configuration at the guard (within 3% of the maximum) at limited locations.

ii) This obstruction applies only to the first run of the stair to the basement.

iii) The headroom obstruction occurs only above a small section of the winder. The stair treads at this location are not negotiable.

iv) Illumination is provided within the stair so that the obstruction is clearly visible.

Dated at Toronto this 13th day in the month of November in the year 1997 for application number 1997-58.

RULING

1. **The Applicant**

   Mr. Theodore Miller, co-owner, Paul Faynwachs and Ted Miller In Trust, 150 Metcalfe Street, Suite 1100, Ottawa, Ontario was issued a building permit under the Building Code Act, 1992 to convert an existing business occupancy to residential at 287 MacLaren Street, Ottawa, Ontario.

2. **Description of Construction**

   The Applicant intends to convert an existing structure, which is more than five years old and is currently classified as Group D - business and personal services occupancy building, to a Group C - residential occupancy. This change would reduce the occupant load from 190 to 40 persons.

   The building is six storeys in building height and has a building area of 1,910 m2 (20,560 ft2). The structure is constructed of noncombustible construction and is equipped with a standpipe

and hose system and a fire alarm system. The ground floor contains an open air garage/parking area with space for eight vehicles, which is open to the exterior at the front and rear of the building. At the front of the front of the parking area is an electronically-controlled security gate, and at the rear is a 1,829 mm (6 ft) high poured concrete wall.

The Applicant proposes to renovate the reminder of the ground floor to provide a lobby for the new residential occupancy. As part of these plans, an exit facility is provided from the floors above leading directly into the parking area. From this door occupants would then travel roughly 15 m (50 ft) to a manual door equipped with panic hardware located within the motorized gate at the garage's entrance.

3. **Dispute** The issue at dispute between the Applicant and the Respondent is whether the proposed exit provides sufficiency of compliance with any of the exit types permitted under Article 3.4.1.4. of the OBC. This provision sets out the types of exit arrangements from any floor area permitted under the Code. Discharging an exit stair into a parking garage does not correspond with the permitted exit types listed in this Article.
4. **Provisions of the Building Code**

3.4.1.4. Types of Exit

(1) Subject to the requirements of this Section, an exit from any floor area shall be one of the following used singly or in combination

(a) an exterior doorway,
(b) an exterior passageway,
(c) an exterior ramp,
(d) an exterior stairway,
(e) an fire escape (as described in Subsection 3.4.7.),
(f) a horizontal exit,
(g) an interior passageway,
(h) an interior ramp, or
(i) an interior stairway.

5. Applicant's Position

The Applicant submitted that the proposed exiting arrangement meets the intent of the Code. Their proposal was submitted under Part 11 of the Code. The Respondent however has been

preventing them from using the more flexible standards found in Part 11. The Applicant, reduced occupant load will decrease the Hazard Index of the building and as a result they believe that the building should be reviewed under the more relaxed Part 11 standards.

The Applicants also indicated that they addressed the Respondent's concern about the means of egress to the front of the building by adding the manual door with the panic hardware in the security gate.

6. **Chief Building Official's Position**

The Respondent submitted that the subject exit does not meet Article 3.4.1.4. of the Code. In their view, the exit facility proposed does not qualify as an exit because it does not meet the requirements included in the definition of exit. They feel the change in major occupancy from Group D to C, as a Renovation Activity #2, requires an evaluation and upgrade of the deficiencies of the early warning and evacuation systems. As they noted, Table 11.3.1.B. requires an evaluation of the "number of exits in other Parts of the Code" and deficiencies upgraded.

As such, the Respondent indicated to the Applicant that they either rectify the deficiencies in accordance with Part 3 of the OBC. Or, using a compliance alternative under Part 11, in accordance with Subsections 11.2.3. and 11.2.4. to the satisfaction of the Chief Building Official, they are requiring that the exit be redesigned to discharge to the exterior.

7. **Commission Ruling**

It is the decision of the Building Code Commission that the evacuation system for the exit through the open air parking area provides sufficiency of compliance with the Building Code provided that:

i) the portion of the path of travel that leads through the open air parking is not more than 9 m in length measured from the exit door to a point at ground level at the perimeter of the building,

ii) measures are taken to prevent vehicles intended to park in spaces adjacent to the path of exit travel from encroaching on the path of exit travel, and

iii) an alternate path of exit travel not leading through the open air parking is available from the interior side of the door opening onto the path of exit travel through the open air parking area.

8. **Reasons**

i) The conditions are consistent with the proposed building code amendments.

ii) The travel distance to a main thorough fare through the parking area is limited to 9 m.

iii) The path of travel is protected from obstruction by vehicles.

iv) An alternate path of exit, not through the parking area, is provided.

Dated at Toronto this 29th day in the month of October in the year 1997 for application number 1997-57.

For the Respondent

RULING

1. **The Applicant**

   Mr. Randy Spiegel, Coordinator of Capital Projects, Associated Hebrew School was issued a building permit under the Building Code Act, 1992 to construct a two storey school in the City of North York, Ontario.

2. **Description of Construction**

   The Applicant presents a two storey, institutional building (with two basement levels), constructed of noncombustible construction. The structure has a total building area of 3,242 m2 (34,900 ft2) and is equipped with a sprinkler system and a standpipe and hose system. The building is classified as a Group A, Division 2 occupancy. It is to be used as a school.

The Applicant proposes that the standpipe and hose system be designed and constructed so that the residual pressure at the topmost fire hose outlet is at least 310 kPa (45 psi) and at the upper basement level at least 413 kPa (60 psi).

3. **Dispute**

The issue at dispute between the Applicant and the Respondent is whether the proposed standpipe and hose system provides adequate water pressure to comply with Sentence 3.2.9.3.(6) of the Ontario Building Code. This provision permits the residual water pressure at the design flow rate at the topmost outlet of a required standpipe and hose system to be less than 450 kPa (65.3 psi) if several conditions are met. (The conditions are noted below.) The Code, however, does not stipulate how much less than 450 kPa the said pressure is allowed to be.

4. Provisions of the Building Code

3.2.9.3. Standpipe and Hose System Design

(6) The residual water pressure at the design flow rate at the topmost outlet of a standpipe and hose system that is required to be installed in a building is permitted to be less than 450 kPa (65.3 psi) provided that

(a) the building is sprinklered in conformance the requirements of Sentence 3.2.5.13.(1),

(b) the water supply at the base of the sprinkler riser is capable of meeting the design flow rate and pressure demand of the sprinkler system, including the inside and outside hose allowance, and

(c) fire protection equipment is available to deliver, by means of the fire department connection, the full demand flow rate at a residual water pressure of 450 kPa (65.3 psi) at the topmost outlet of the standpipe and hose system.

5. Applicant's Position

The Applicant submitted that the standpipe and hose design fully complies with OBC Sentence 3.2.9.3.(6). As they note, the building is fully sprinklered, even though this is not required under the Code. Moreover, the standpipe and hose system is only required, they argue, because of the two storey basement.

In their view, the designed residual pressure of at least 310 kPa (45 psi) at the topmost cabinet on the second floor and 413 kPa (60 psi) at the basement level is satisfactory. The Applicant presented hydraulic calculations to support their claims.

6. Chief Building Official's Position

The Respondent submitted that the proposed design for the standpipe and hose system does not comply with the Code. While they recognize that Sentence 3.2.9.3.(6) does not stipulate a minimum water pressure of 450 kPa (psi), they feel that a pressure of 310 kPa (psi) is too low. The standpipe and hose system is intended for occupants to fight incipient fires, but the Respondents believe that the inadequate pressure makes the system potentially hazardous to individuals who attempt to use it.

They also feel that the sprinkler system is not a mitigating factor since it would not be activated at the time of incipient firefighting by occupants.

7. **Commission Ruling**

It is the decision of the Building Code Commission that standpipe and hose system complies with Sentence 3.2.9.3.(6) of the Building Code.

8. **Reasons**

i) The building is sprinklered in conformance with the requirements of Sentence 3.2.5.13.(1).

ii) The water supply at the base of the sprinkler riser is capable of meeting the design flow rate and pressure demand of the sprinkler system, including the inside and outside hose allowance, and

iii) Fire protection equipment is available to deliver, by means of the fire department connection, the full demand flow rate at a residual water pressure of 450 kPa (65.3 psi) at the topmost outlet of the standpipe and hose system.

iv) The building requires only standpipe and hose in the basements under 3.2.9.1.(b) of the Building Code.

v) The fire safety plan should not contemplate the use of standpipe and hose system by occupants.

RULING

1. **The Applicant**

   Mr. Walter Alley, Homeowner, 9700 Menard Street, is an individual to whom a correction order was issued under the Building Code Act, 1992 to install vapour barrier and insulation in the walls and ceiling of a space formerly used as a external atrium at 9700 Menard Street, Windsor, Ontario.

2. **Description of Construction**

   The Applicant is the owner of a Group C - residential condominium unit at 9700 Menard Street, Windsor, Ontario that was constructed approximately 10 years ago. The condominium complex comprises several buildings, each containing a number of units. The Applicant's unit is one of six in his building. The total building areas of the subject unit and the larger building are 1,525 ft2 and 8,700 ft2 respectively. The unit and the building are one storey in building height and are constructed of combustible construction.

The Applicant's unit, when originally constructed, contained a rectangular open-air, non conditioned, atrium located roughly in the centre of the subject unit. The atrium space measures 90 ft2. It is accessed by two sliding glass doors at opposite ends of the atrium.

Concerned about an alleged leak in the basement at the site of the atrium, the Applicant applied for and received a building permit in July, 1996 to enclose the open space. Accordingly, the Applicant had a roof constructed over the atrium. The construction of the roof was 2 x 6 in. framing members at 18 in. on centre with 3/8 in. spruce sheathing on the roof. The roof was finished with new shingles, patched into the existing roof system. Three 21 x 46 in. velux skylights were also installed in the atrium roof. The construction did not include insulation and vapour barrier in the walls and ceiling. Heating and air conditioning facilities were also not provided in this previously non-conditioned space.

3. **Dispute**

The dispute between the Applicant and Respondent is whether the recent construction to enclose the atrium should comply with Article 9.25.2.4. and Sentence 9.25.2.7.(4). These provisions set out requirements for the location of insulation and minimum standards for thermal resistance for glazed areas. Both provisions provide standards that are concerned with the separation of heated (conditioned) and unheated (non-conditioned) space. Central to this issue is whether the newly enclosed atrium constitutes a conditioned space or not.

4. **Provisions of the Building Code**

Thermal Insulation and Control of Condensation

9.25.2.4. Location of Insulation

Insulation shall be provided between heated and unheated spaces and between heated spaces and the exterior, and around the perimeter of concrete slabs-on-ground.

9.25.2.7. Minimum Thermal Resistance

(4) All glazing that separates heated space from unheated space shall have a thermal resistance of not less than 0.30m2.C/W (1.70 ft2.h.0F/Btu).

5. **Applicant's Position**

The Applicant submitted that the construction to enclose the open-air atrium does not create a conditioned space. In their view, their permit application was simply for a roof to create an enclosed atrium. They note that it was never their intention to use this area as interior, conditioned space. As a result, no heating or air-conditioning facilities were applied for, nor provided to the enclosed space. The covered atrium, they contend, is closed and not in use in the winter.

Moreover, the roof construction was essential the Applicant argues due to the severe water leaking at the atrium area into the basement of his unit. the Applicant notes that the roof construction has stopped the leaks.

6. **Chief Building Official's Position**

The Respondent submitted that by constructing a roof and enclosing the atrium, the area becomes a conditioned space and is therefore required to comply with Article 9.25.2.4. and Sentence 9.25.2.7.(4). In their view, the enclosing of the atrium makes that space "open" to the dwelling. As a result, the provisions of Section 9.25 of the OBC should apply.

Specifically, the Respondent feels that the new atrium roof is now separating a heated space from a non-heated space and is thus required to provide sufficient thermal insulation to prevent moisture condensation, especially in the winter. In addition, they believe that the walls and ceiling of the enclosed atrium, which should be appropriately insulated, are required to have a vapour barrier to prevent the diffusion of water vapour from attic and roof spaces.

The Respondent is also contending that much of the work was carried out without the proper municipal building inspections.

7. **Commission Ruling**

It is the decision of the Building Code Commission that the enclosure of an existing open court provides sufficiency of compliance with Section 9.25 of the Building Code provided the unheated space is ventilated in accordance with Article 9.32 of the Building Code.

8. **Reasons**

i) The Building Code Commission considers the court to be an unconditioned space. The enclosed court (Atrium) is unheated, and the enclosing walls do comply with Section 9.25 for thermal design.

ii) Evidence provided by the owner indicated that the space would be used as an unconditioned space.

Leber/Rubes Inc.,

RULING

1. **The Applicant** Mr. Robert Woodman is a person who has applied for a building permit under the Building Code Act, 1992 to renovate a retail shopping mall by infilling two existing floor openings by adding a glass paver floor assembly at the St. Laurent Shopping Centre, 1200 St. Laurent Blvd., Ottawa, Ontario.
2. **Description of Construction**

   The St. Laurent Shopping Centre is approximately 81,290 m2 (875,000 ft2) in building area. It is two storeys in building height, with one basement level. It is constructed of noncombustible construction. The floor assemblies have a 2 h fire-resistance rating.

   The Centre has several major occupancies; Group E - mercantile (retail), Group D - businesses and personal services (offices, salons and banks, etc.), Group A, Division 1 - assembly occupancies for viewing performing arts (movie theatres), and Group A, Division 2 - assembly occupancies not elsewhere classified (career training centres).

   The building is equipped with a two-stage fire alarm system. It also has a sprinkler system, a standpipe and hose system, and a smoke control system in the South Court area.

The Applicant proposes to infill two existing openings between floor levels, both are located in the public corridor of the shopping centre's South Court, on either side of the main escalators. The openings are approximately 3 m by 7.5 m (10ft by 25ft) and the Applicant proposes to close these over with a floor assembly constructed of solid glass floor pavers supported by structural steel members. The guards around the existing openings will be removed.

3. **Dispute**

The issue at dispute between the Applicant and the Respondent is whether the glass floor paver assembly provides sufficiency of compliance with Sentence 3.2.2.45.(2) of the Ontario Building Code. Sentence 3.2.2.45.(2) requires that buildings that must comply with this provision must be of noncombustible construction and that the floor assemblies shall be fire separations with a 2 h fire-resistance rating. The subject floor assembly has not been tested against the requirements of CAN 4-S101-M, "Standard Methods for Fire Endurance Tests of Building and Construction Materials" for a two hour fire-resistance rating.

4. **Provisions of the Building Code**

Sentence 3.2.2.45.(2) Mercantile Buildings, up to 6 Storeys

(2) The building shall be of noncombustible construction, and

(a) floor assemblies shall be fire separations with a fire-resistance rating of not less than 2 h, (b) mezzanines shall have a fire-resistance rating of not less than 1 h, (c) roof assemblies shall have a fire-resistance rating of not less than 1 h, and (d) all loadbearing walls, columns and arches shall have a fire-resistance rating not less than that required for the supported assembly.

5. **Applicant's Position**

The Applicant submitted that the glass and steel floor assembly, in conjunction with additional safety measures, provides sufficiency of compliance with Sentence 3.2.2.45.(2). Under non-fire conditions, they note that the assembly as a whole will be designed to ensure that the structural sufficiency of the floor will meet the requirements for dead and live loads.

They have also designed the assembly to be safe in a fire. The steel members, for example, will be protected with either spray-on fire proofing, boxed gypsum board construction, or intumescent paint. Further, the path of travel on both sides of the subject floor assemblies will be at least 3 m (10 ft) from the glass pavers to the store fronts on either sides. In effect, this would

create aisles on both sides of the infilled areas that would meet the standards under the OBC for kiosks in a public corridor more than 9 m wide. Occupants would therefore have an adequate path of travel in the event of an emergency.

In addition, the Applicants propose several measures to protect the glass paver assemblies. They plan to install close-spaced quick response sprinklers around the infilled areas according to 4-5.3.4 of NFPA 13. The sprinklers surrounding both glass paver assemblies will be separately zoned and electronically supervised by the fire alarm system. In conjunction with the sprinklers, they propose to install noncombustible draft stops as per NFPA 13, as well as additional smoke detectors that are designed to activate the smoke exhaust system. The Applicants are also proposing to install supplementary sprinklers below the glass floor areas to provide continuity of the Centre's sprinkler system. They note that by closing the openings in combination with these measures, occupants and fire fighters on the higher levels may in fact be more protected from fire below than previously.

The Applicants also point to the fact that the South Court area of the mall is equipped with a smoke exhaust system that is intended to reduce the spread of smoke to other parts of the building. This system will reduce smoke accumulation by venting it through the roof, which will enhance visibility and general safety during a fire.

A fire safety plan is currently being developed for the St. Laurent Shopping Centre. This plan will consider the locations and special protection for the glass floor paver assemblies. As well, a floor plan indicating these assemblies will be posted in the appropriate locations.

Finally, the Applicants note that a similar floor assembly was installed in the BCE Place in Toronto.

6. **Chief Building Official's Position**

The respondent submitted that in the absence of test data confirming whether the glass floor paver assembly meets the CAN 4-S101-M standards, it is their belief that they do not possess the authority to approve this proposal. In their view, the infill construction should provide a 2 h fire-resistance rating as per Sentence 3.2.2.45.(2). Further, without any substantiation of the adequacy of the subject assembly, they are still requiring that the areas be provided with appropriate guards according to Clause 3.3.1.17.(1)(c).

7. **Commission Ruling**

It is the decision of the Building Code Commission that the proposed glass paver floor assembly provides sufficiency of compliance with Articles 3.2.2.45 and 3.3.1.17 of the Building Code provided:

i) quick response sprinklers are installed in accordance with NFPA 13-1991 and

ii) draft stops are installed in accordance with the requirements of the Building Code.

8. **Reasons:**

i) Article 3.2.8.2. allows the first and the storey above or below it to be interconnected by virtue of an unprotected floor opening in a Group E major occupancy provided the interconnected floors are sprinklered.

ii) evidence was provided that the glass paver floor system has been designed specifically as a floor assembly and is capable of supporting required dead and live loads.

iii) the steel structure supporting the glass paver floor assembly will have a 2 hour fire resistance rating.

iv) A smoke exhaust system is installed that will enhance visibility for fire fighting and occupant evacuation.

v) the nature of the floor assembly will be documented as part of the fire safety plan.

vi) floor plans noting the glass block floor assembly will be provided at all exits used for fire fighting.

For the Respondent

RULING

1. **The Applicant**

   Mr. Galli Tiberini is a person who has applied for a building permit under the Building Code Act, 1992 to construct two residential buildings 4 and 6 storeys in height using the 100 mm Royal Building System wall construction, at the Piazza Woodbridge Residences, 53 Woodbridge Avenue, Vaughan (Woodbridge), Ontario.

2. **Description of Construction**

   The Applicant proposes to construct residential condominium buildings, 4 and 6 storeys in building height. Buildings A and B have building areas of 691 m2 and 2,236 m2 respectively. Both buildings are constructed of noncombustible construction. Each building is equipped with a

standpipe and hose system and a fire alarm system. Neither building however contains a sprinkler system, except in the basements.

As part of this renovation, the Applicant is proposing to utilize the 100 mm Royal Building System as the exterior wall/cladding assembly. Similar to pre-cast concrete, this cladding assembly requires that prefabricated wall panels be filled with concrete and attached to the exterior of the building. The casting of the wall panels is done by pouring concrete between two PVC forms held in place by many PVC cross-webs.

There are two proposed exterior wall/cladding assemblies. Assembly #1 on the outside comprises a 100 mm thick concrete panel prefabricated in PVC forms. The exterior of the PVC form is covered with a cementitious coating (a mixture of Type 10 Portland cement and Durock Prep Coat) reinforced with an applied fabric as the final finish. The inside of this assembly is made of 152 mm of thick batt insulation, vapour barrier, and 15.9 mm Type X gypsum wallboard mechanically fastened to steel studs. Assembly #2 is similar to #1 but an additional 50 mm expanded polystyrene rigid insulation is added to the external surface of the concrete panel. The same cementitious coating is applied to the exterior of the insulation.

3. **Dispute**

The issue at dispute between the Applicant and respondent is whether the proposed exterior wall/cladding assemblies provide sufficiency of compliance with Article 3.1.5.5. of the Ontario Building Code. This provision, which applies to a building that must be of noncombustible construction, does not permit an exterior non-loadbearing wall assembly, which includes combustible cladding components, to be used on a six storey building unless three conditions are satisfied.

These conditions, found in Sentence (1), are that the building must be sprinklered, the interior face of the wall assembly is protected by an appropriate thermal barrier, and that the wall assembly meets the test standards for flame spread and heat flux. Sentence (9) however eliminates these restrictions when adequately protected foamed plastic insulation is used in the wall assembly.

4. **Provisions of the Building Code**

Article 3.1.5.5. Combustible Cladding

(1) Except as provided in Sentence (9) or where noncombustible cladding is required by Subsection 3.2.3., an exterior non-loadbearing wall assembly that includes combustible cladding components is permitted to be used in a building required to be of non-combustible construction that is not more than 3 storeys in building height, if not sprinklered, and not more than 6 storeys in building height, if sprinklered, provided the interior surfaces of the wall assembly are protected by a thermal barrier conforming to Sentence 3.1.5.11.(3) and the wall assembly satisfies the criteria of Sentences (5) and (6) when subjected to testing in conformance with Sentences (2) to (4).

(2) The fire testing required by Sentence (1) shall be conducted on a wall assembly that (a) is not less than 5 m (16 ft 5 in) wide and not less than 10 m (32 ft 10 in) high with an opening 2.5 + 0.1 m (8 ft 2 in + 4 in) wide by 1.4. + 0.1 m (4 ft 7 in + 4 in) high, located in the middle of the assembly not more than 3 m (9 ft 10 in) above the lowest edge,

(b) is representative of the exterior wall construction, except for the interior finish, and

(c) incorporates horizontal and vertical joints not more than 3 m (9 ft 10 in) vertically above the opening.

(3) The wall assembly shall be exposed on its exterior face to a flame issuing from the opening that, on a noncombustible wall having a density of not less than 700 kg/m3 (44 lb/ft3) to a depth of 12 mm (1/2 in) from the exposed surface, generates an average heat flux between

(a) 42 and 48 kW/m2 (13,300 and 15,200 Btu/ft2h) measured 0.5 m (19 in) above the opening, and

(b) 25 and 29 kW/m2 (7930 and 9190 Btu/ft2h) measured 1.5. m (4 ft 11 in) above the opening.

(4) The duration of exposure to the flame specified in Sentence (3) shall be not less than 15 min following a 5 min gradual heat flux increase and preceding a 5 min gradual cooldown period after the flame exposure.

(5) Flaming on or in wall assembly shall not spread more than 5 m (16 ft 5 in) above the opening during or following the flame exposure of 25 min.

(6) The heat flux during the flame exposure on a wall assembly shall be not more than 35 kW/m2 (11,100 Btu/ft2h) measured 3.5. m (11 ft 6 in) above the opening.

(7) A wall assembly permitted by Sentence (1) that includes combustible cladding of fire-retardant treated wood shall be tested for fire exposure after the cladding has been subjected to an accelerated weathering test as specified in ASTM D2898, "Test Method for Accelerated Weathering of Fire-Retardant Treated Wood for Fire Testing".

(8) Wood decorative cladding is permitted to be used on exterior canopy fascias of a building required to be of noncombustible construction provided it is fire-retardant treated wood that has been, before testing, conditioned in conformance with ASTM D 2898, "Test Method for Accelerated Weathering of Fire-Retardant Treated Wood for Fire Testing", and the canopy is

(a) a first floor canopy, or

(b) not more than 6 m (19 ft 8 in) above ground level

(9) The requirements in this Article do not apply where foamed plastic insulation is used in an exterior wall assembly of a building and the insulation is protected in conformance with Clause 3.2.3.7.(3)(a).

5. **Applicant's Position**

The Applicant submitted that the proposed wall/cladding assembly provides sufficiency of compliance with Article 3.1.5.5. of the OBC. In their opinion, the fuel content of the PVC in these wall systems presents less of a hazard than the foamed plastic insulation currently allowed in exterior walls under Sentence 3.1.5.5.(9) of the OBC. They argue that the PVC in assemblies #1 and #2 will be protected from both sides. The interior sheet of PVC is protected by the Type X (15.9 mm, 5/8 in) drywall mounted on steel studs. The exterior PVC sheet and polystyrene insulation (in the case of assembly #2) will be protected by the Durock finish which will be applied in accordance with ULC listing EW20 designed for protection of exterior claddings.

The Applicants also hold that assembly #2 meets the requirements of Sentence 3.1.5.5.(9) regarding foamed plastic insulation which is appropriately protected according to Clause 3.2.3.7.(3)(a). As a result, they feel that the requirements of Article 3.1.5.5. should not apply to this assembly.

6. **Chief Building Official's Position**

The Respondent submitted that the proposed wall/cladding assemblies do not provide sufficiency of compliance with Article 3.1.5.5. They argue that all of the conditions set out in Sentence

3.1.5.5.(1) for a building of six storeys to permit combustible elements in an exterior cladding have not been met. The building is not sprinklered and the appropriate testing has not been done. As a result, the PVC forms and webbing used in these assemblies is a combustible component found in a wall assembly that is required to noncombustible since all conditions have not been met.

They disagree with the Applicant's assertion that because of its foamed plastic insulation, assembly #2 is permitted under Sentence 3.1.5.5.(9) to have the aforementioned conditions waived. In their view, the requirements to protect the insulation in an exterior wall assembly found in Clause 3.2.3.7.(3)(a) are only for the foamed plastic insulation found in that assembly and not other combustible materials, i.e. the PVC in the Royal Building System exterior wall construction.

7. **Commission Ruling**

It is the decision of the Building Code Commission that the exterior cladding panel not containing foam plastic on the exterior face must comply with the provisions of Article 3.1.5.5. of the Building Code

AND

It is the decision of the Building Code Commission that the exterior cladding panel with foam plastic on the exterior face must comply with Sentence 3.2.3.7.(3)(a) and if the option of 3.2.3.7.(3)(a)(ii) is selected, a test of the complete assembly is required to demonstrate compliance.

8. **Reasons**

i) The panel not containing foam plastic on the exterior face contains combustible cladding components and thus is subject to Article 3.1.5.5.

ii) Based on evidence provided, the panel containing foam plastic on the exterior face (under the current wording of Clause 3.1.5.5.(a) of the Building Code) is exempt from compliance with Article 3.1.5.5. but requires compliance with Clause 3.2.3.7.(3)(a) of the Building Code.

iii) This decision is specific for this application only.

Dated at Toronto this 9th day in the month of October in the year 1997 for application number 1997-53.

RULING

1. **The Applicant**

   Mr. Harvey Fruitman, Executive Vice President, Torresdale Construction is a person to whom a building permit was issued under the Building Code Act, 1992 to renovate existing rental townhouse units into residential condominiums, at Countrylane Townhomes, Aurora, Ontario.

2. **Description of Construction**

   The Countryland Townhomes is a 38,707 m2 (9.565 acres) site, divided into twelve blocks, with a total of 200 rental townhouse units, consisting of 28,182 m2 (303,363.18 ft2) of building area.

   There are three types of townhouse suites; 100 A3 suites, 81 B3 suites, and 19 C3 suites. The approximate sizes of A3, B3 and C3 units are 145 m2 (1,558.32 ft2), 130 m2 (1,398.32 ft2) and 168 m2 (1,803.54 ft2) respectively. All suites are 3 storeys in building height.

The townhouse units are constructed of combustible construction. There are 2 parking spaces provided in the front of all A3 units at grade level. These parking spaces are intended for both the A3 suites as well as the adjoining B3 or C3 units, which are attached to the A3 units on the side opposite to the parking facilities. The subject parking areas are currently covered by a concrete deck and are separated by concrete block walls into garage-like car bays that can accommodate two vehicles. Both the A3 suites and the attached B3 or C3 units have an exit into this open-ended garage area. For the A3 units, this is the only exit currently provided.

The other unit types have an additional exit on their side of the building. The deck space above the parking area, which is attached to the second floor of the A3 suites, is currently used as a series of narrow patios which are abutted by a long, open-air corridor.

The proposed renovation would convert the townhouse units into residential condominiums. The work planned would divide the existing double car bays with 1 h fire separations into single vehicle garages which would also have steel overhead garage doors added to the openings to completely enclose the parking space. Drywall on the ceiling of all garages would be upgraded as well. The narrow patios and the long, external corridors would be replaced by larger patios that would cover the full concrete deck areas. It is proposed that pairs of A3 units share an exterior exit stair that would be accessible from the second storey patio area of both units. To maintain the continuity of the existing outside passageway for the exterior exit stairs, it is also proposed that bi-swinging gates be installed between the patios of the A3 units. This would allow the occupants of each A3 suite the option of choosing between several exit stairs in an emergency. The Applicant is also proposing to install hard-wired smoke detectors in all Countrylane Townhome units.

Countrylane Townhomes are classified as having a Group C - residential major occupancy. Many of the blocks and townhouse units are subject to Part 9 of the Building Code, however some portions of certain blocks exceed 600 m2 in building area and are therefore subject to Part 3.

3. **Dispute**

The issue at dispute between the Applicant and Respondent is whether the proposed renovations provide sufficiency of compliance with Sentences 3.2.5.5.(1), 3.2.5.6.(4) and Article 9.10.19.3., Articles 3.3.4.4. and 9.9.9.1., and Sentence 3.2.3.13.(2) and Article 9.9.4.4. of the Ontario Building Code. The partition of the double bays into single car garages and the placement of

garage doors at their openings blocks the only exterior exit door for the A3 suites. The proposed blocking of this exit creates three issues.

The first issue revolves around whether there is appropriate fire department access. Sentence 3.2.5.5.(1) requires that buildings over 600 m2 in building area provide access routes for fire department vehicles to the principle entrance and to each building face with required access openings. Sentence 3.2.5.4.(6) requires that a portion of a building that is cut off without access from the remainder of the building be not more than 45 m from fire fighting vehicle to the entrance of the remote area. Article 9.10.19.3. provides similar requirements for Part 9 buildings. It reiterates that access for fire fighting equipment shall be provided to each building by a street, private roadway or yard. The blocking of the A3 unit's parking level entrances has meant that the fire department access has been limited, and in the case of some buildings suites are farther than the permitted 45 m.

The second issue regarding the installation of the garage doors is the provision of a means of egress through the construction of a new second storey, shared exterior stairs proposed for the A3 units. Articles 3.3.4.4. and 9.9.9.1. of the OBC set out the egress standards from a dwelling unit in Part 3 and Part 9 buildings respectively. In particular, Article 3.3.4.4 requires that an egress door be provided on the uppermost and lowest storey of a dwelling unit unless certain conditions are met. As well, the "stacked" nature of the townhouses may not satisfy Sentence 9.9.9.1.(2), which requires that the travel distance be not more than one storey if there is no dwelling unit above or below. The proposed exit doorways are also higher than the 1.5 m allowed in both Articles 3.3.4.4. and 9.9.9.1. Also in dispute is Sentence 3.3.4.4.(2) which requires that a dwelling unit's exit door shall open directly into a public access to an exit. The proposal to replace the long corridors fronting the narrow patios with enlarged, connected patios may not be consistent with a public access to an exit.

The third issue is that the proposed new shared exterior egress stairs pass within roughly 1 m of the garage door openings and may result in dangerous exposure to a fire originating in a garage. Sentence 3.2.3.13.(2) requires that openings in the exterior wall of a building located within 3 m horizontally of an unenclosed stair serving that building which may cause a hazard to such stairs shall be protected with wired glass or glass block. Article 9.9.4.4. provides the same standards for Part 9 buildings.

4. **Provisions of the Building Code**

Sentence 3.2.5.5.(1) Access Routes

(1) Every building which is more than 3 storeys in building height or more than 600 m2 (6460 ft2) in building area shall be provided with access routes for fire department vehicles

(a) to the principal entrance, and
(b) to each building face having access openings for fire fighting as required in Articles 3.2.5.1. and 3.2.5.2.

Sentence 3.2.5.6.(4) Location of Access Routes

(4) Where a portion of a building is completely cut off from the remainder of the building so that there is no access to the remainder of the building, the access routes required by Sentence (2) shall be located so that the unobstructed path of travel from the vehicle to one entrance of each such portion is not more than 45 m (147 ft 8 in).

Article 9.10.19.3 Fire Department Access to Buildings

(1) Access for fire department equipment shall be provided to each building by means of a street, private roadway or yard.

(2) Where access to a building as required in Sentence (1) is provided by means of a roadway or yard, the design and location of such roadway or yard shall take into account connection with public thoroughfares, weight of fire fighting equipment, width of roadway, radius of curves, overhead clearance, location of fire hydrants, location of fire department connections and vehicular parking.

Article 3.3.4.4. Egress from Dwelling Units

(1) Single storey dwelling units in apartment buildings need not lead to a public corridor or exterior passageway on the same storey provided the dwelling units are served by private stairways leading directly to a public access to exit on the storey

(a) immediately above, and (b) immediately below. (2) Except as provided in Sentences (3) and (4), every dwelling unit containing more than 1 storey shall have an exit door or an egress door opening directly into a public access to exit from the uppermost storey and from the lowest storey of the dwelling unit so that the floor level of each such storey is served by an exit or egress door located not more than 1.5 m (4 ft 11 in) above or below the floor level.

(3) A single exit is permitted from a dwelling unit provided the exit is an exterior doorway not more than 1.5 m (4 ft 11in) above adjacent ground level and (a) it is not necessary to travel up or down more than 1 storey to reach the exit door, or (b) the uppermost floor level opens to a balcony not more than 6 m (19 ft 8 in) above adjacent ground level.

(4) An a egress door from either the uppermost storey or the lowest storey in a dwelling unit, as required in Sentence (2), need not be provided

(a) where that storey is served by a stairway that

(i) leads to a public access to exit,

(ii) has not direct access to any other storey in the dwelling unit, and

(iii) is separated from the other storeys in the dwelling unit by a fire separation having a fire-resistance rating of not less than 45 min, or

(b) where a smoke alarm conforming to Article 3.2.4.21. is installed

(i) on the uppermost storey of a dwelling unit having not more than 2 storeys above the first storey of the building, or

(ii) on each storey of the dwelling unit provided it is not necessary to travel either more than 18 m (59 ft 1 in), or more than 1 storey up or down to reach the egress door.

(5) In buildings of residential occupancy not more than 3 storeys in building height, a doorway from a dwelling unit is permitted to open directly into an exit stairway provided such dwelling unit has a second and separate means of egress.

(6) A doorway from a dwelling unit may open onto an interior corridor served by a single exit, or an exterior balcony served by a single exit stairway, or an exterior passageway served by a single exit stairway provided each dwelling unit has a second and separate means of egress.

Article 9.9.9.1 Travel Limit to Exits or Egress Doors

(1) Except as provided in Sentences (2) and (3), every dwelling unit containing more than one storey shall have a sufficient number of exits of egress doors so that it shall not be necessary to travel up or down more than 1 storey to reach a level served by

(a) an egress door to a public corridor, enclosed exit stair or exterior passageway, or (b) an exit doorway not more than 1.5 m (4 ft 11 in) above adjacent ground level. Sentence 3.2.3.13.(2) Protection of Exit Facilities (2) Where an unenclosed exterior exit stair or ramp may be exposed to fire from openings in the exterior walls of the building it serves, the openings in the exterior walls of the building shall be protected with wired glass in fixed steel frames or glass block conforming to Article 3.1.8.14. where the openings in the exterior walls of the building are within 3 m (9 ft 10 in) horizontally and

(a) less than 10 m (32 ft 10 in) below the exit stair or ramp, or (b) less than 5 m (16 ft 5 in) above the exit stair or ramp. Article 9.9.4.4. Openings Near Unenclosed Exit Stairs and Ramps.

Where an unenclosed exterior exit stair or ramp provides the only means of egress from a suite, and is exposed to fire from openings in the exterior walls of another fire compartment, the openings in the exterior walls of the building shall be protected with wired glass in fixed steel frames or glass block conforming to Articles 9.10.13.5. and 9.10.13.7. when the openings in the exterior walls of the building are within 3 m (9 ft 10 in) horizontal

5. **Applicant's Position** The Applicant submitted that the proposed renovations provide sufficiency of compliance with the above listed provisions. Regarding the issue of fire department access, for the Part 3 buildings they recognize that the 45 m limit between the entrance of a cutoff unit and a fire department vehicle may not be met. Instead, they rely on Sentence 11.3.5.1.(1). This provision deals with extended buildings and it would allow them to utilize compliance alternative C22.

   This alternative states that for "buildings 6 storeys and less, existing access to existing occupancy is acceptable..." This would permit the Applicant to close over the garage entrances and construct new exit stairs without providing additional measures to compensate for the lesser access. Considering the Part 9 buildings under the same extended buildings provision, the Applicants propose to employ compliance alternative C153 to the same effect. In their view, the extended buildings meet the intent of the OBC, and roughly 90 per cent of the units meet the literal requirements of the Code.

   Since the issue of providing an exit from the A3 suites requires the construction of new exterior exit stairs, the Applicant relies not upon compliance alternatives but new construction provisions in Parts 3 and 9. To address the requirement of providing an exit from the uppermost and lowest floors of the unit found in Sentence 3.3.4.4.(2), the Applicants propose to install a hard-wired 120 volt interconnected smoke alarm on each floor of all dwelling units as per Subclause

3.3.4.4.(4)(b)(i). In their view, this would preclude the necessity for uppermost and lowest floor exits.

For the Part 9 buildings, they argue that egress could be accommodated under Clause 9.9.9.1.(1)(b) or Sentence 9.9.9.1.(2). The first provision allows dwelling units with more than 1 storey to have a sufficient number exits so that it is not necessary to travel up or down more than 1 storey to reach a level served by an exit doorway that is not more than 1.5 m (4 ft 11 in) above the adjacent ground. (The Applicant does admit however that the proposed second level exit door is higher than 1.5 m. This issue is not addressed.) The Applicant also notes that Sentence 9.9.9.1.(2) allows travel distance to be greater than 1 storey if the floor level is served by openable windows. This should afford them some greater flexibility in interpreting the exiting arrangements they have provided. Further, these units will also have the interconnected, hard-wired smoke alarm system.

Concerning the issue of the door opening into an access to exit as required under 3.3.4.4.(2), the Applicants argue that having two dwelling units share an exit stair to the ground level is similar to many exiting arrangements in older buildings. They also argue that the continuity of the exterior passageway will be maintained due to the bi-swinging gates that are proposed to be installed between the patios. This continuity of the passageway will give occupants access to two or more exterior exit stairs. Overall, it is their opinion that the exiting as designed meets the intent of the Code.

The Applicants believe that they have addressed the issue of exposure to the exterior stair as well. They note that the new exiting arrangements would offer occupants many escape options in an emergency, thereby avoiding stairs that may present hazards. The garages will be divided with 1 h fire separations and will have upgraded drywall on the ceilings. The new garage doors, they argue, will also offer some protection. Lastly, they point to the concrete block fire separations between the units and the proposed smoke alarm system which they feel will give the entire site a good level of fire protection.

6. **Chief Building Official's Position**

The Respondent submitted that the proposed renovations did not provide sufficiency of compliance with the provisions discussed and in some instances place the buildings into situations of non-compliance. They reject compliance alternatives C22 and C153 which depends on maintaining the existing access because, in their view, the proposed addition of garage doors blocks off the existing access. While adding garage doors may be deemed to be "extending the

building", the Respondent argues however that this particular extension substantially changes the existing access that the alternative allows as acceptable.

The municipality believes that the exiting requirements have not been satisfied. For the Part 3 buildings, they hold that the proposed second floor door does not open into an access to an exit. In their opinion, the linked patios do not constitute an access to an exit, nor a passageway. In fact, they are concerned that the balconies may support potential obstacles for exiting such as bar-be-ques, furniture and other accessories. In the Part 9 structures the Respondent does not believe that travel distances allowed in Sentence 9.9.9.1.(2) due to openable windows can be considered legitimate due to their contention that as stacked townhouses there are dwelling units above and below other units.

The Respondent also argues that the stairs do not meet the provisions regarding exposure to exterior exit stairs. The creation of the external stairs only serves to add to the non-compliance of the townhouse suites. The result of this proposal would be a reduction in safety due to potential fire exposure. They also feel that the stairs, as external exits, present dangers during inclement weather such as wind, rain and ice. This would be especially an issue for visitors unfamiliar with the stairs and who will often not be able to use the garage entrance.

7. **Commission Ruling**

It is the decision of the Building Code Commission that the proposed renovations provide sufficiency of compliance with Sentence 9.9.9.1.(1), Articles 3.3.4.4., 9.10.19.3. and Subsection 3.2.5.

8. **Reasons**

i) Additional exterior stairways will be provided to improve fire department access and exiting from the 3A dwelling units.

ii) Hard-wired smoke alarms will be provided on every level and interconnected within each dwelling unit.

iii) Garages within each dwelling unit will be separated from each other by construction having a 1 hour fire resistance rating.

iv) Occupant safety is not reduced consistent with the intent of Part 11 of the code.

Dated at Toronto this 9th day in the month of October in the year 1997 for application number 1997-51.

BCC Ruling No. 97-43-585

BUILDING CODE COMMISSION DECISION ON B.C.C. #97-43-585

IN THE MATTER OF Subsection 24 (1) of the *Building Code Act, 1992.*

AND IN THE MATTER OF Sentence 3.2.1.4.(1) and 3.2.1.4.(2) of "the Building Code" (Ontario Regulation 419/89 as amended by Ont. Reg. 183/88, 581/88, 11/89 and 115/89).

AND IN THE MATTER OF an application by Mr. Robert Riddell, Senior Technical Specialist, Algoma Steel Inc., 105 West Street, Sault Ste. Marie, Ontario, for the resolution of a dispute with Mr. Maurice Kukoraitis, Director of Engineering, City of Sault St. Marie, Ontario, concerning whether the floor assemblies above the oil cellar and caster basement provide sufficiency of compliance with Sentences 3.2.1.4.(1) and (2) of the Ontario Building Code (OBC), whether the openings in the said floor assemblies provide sufficiency of compliance with Sentence 3.1.8.1.(2) of the OBC, and whether the number of exits from the caster basement provide sufficiency of compliance with Sentence 3.4.2.1.(2) at the Direct Strip Production Complex, Algoma Steel Inc., 105 West Street, Sault Ste. Marie, Ontario.

RULING

1. **The Applicant**

   Mr. Robert Riddell, Senior Technical Specialist, Algoma Steel Inc, is a person who has been issued an order to comply under the Building Code Act, 1992 to bring the floor assemblies over the oil cellar and the caster basement of a recent addition in conformity with certain provisions of the Ontario Building Code at the Direct Strip Production Complex, Algoma Steel Inc., 105 West Street, Sault Ste. Marie, Ontario.

2. **Description of Construction**

The existing building is a three and four storey industrial structure with an area of approximately 60,380 m2 (650,000 ft2). The addition, constructed between 1996 and 1997, has added another 32,520 m2 (350,000 ft2) to the structure making the current total building area 92,900 m2 (1,000,000 ft2).

The building is constructed of noncombustible construction. It is equipped with a fire alarm system. The building also has a partial sprinkler system, only in the oil cellar of the addition. It does not have a standpipe and hose system.

Within the addition there are two large depressed areas in the main floor. These areas are known as the oil cellar and the caster basement. They are located beneath the addition's major production and processing equipment and are used for servicing the machinery above and the accommodation of ancillary equipment. The floor assemblies above the oil cellar and caster basement are concrete slab supported with unprotected steel beams.

Both the existing building and the addition are considered to have a Group F, Division 3 (low hazard industrial) major occupancy. The structure, including the addition, is used to manufacture steel slabs.

3. **Dispute**

There are three issues at dispute between the Applicant and the Respondent. The first is whether the floor assemblies above the oil cellar and the caster basement provide sufficiency of compliance with Sentences 3.2.1.4.(1) and (2). These provisions of the OBC require that a floor assembly above a basement must be constructed as a fire separation with a fire-resistance rating as determined in Subsection 3.2.2., but not less than 45 min. The supporting elements supporting the subject floor assembly are required to have the same fire-resistance rating as the floor. While the concrete slab floor above the oil cellar and caster basement in the Direct Strip Production Complex may provide the necessary 45 minute rating, the steel supporting beams for these floor assemblies are unprotected and therefore do not have a resistance rating.

The second dispute is whether the openings in the said floor assemblies provide sufficiency of compliance with OBC Sentence 3.1.8.1.(2), which requires that all openings in fire separations must be protected with closures. The openings at the oil cellar and the caster basement do not have closures. There are large numbers of pipes that access the mill stands, and in so doing create many openings between floor levels. As well, the steel production equipment in some

areas of the complex forms part of the floor, and as it moves it periodically exposes the basement.

The last dispute is over whether the number of exits from the caster basement of the Direct Strip Production Complex provide sufficiency of compliance with Sentence 3.4.2.1.(2) of the Code. This provision allows a floor area in a Group F, Division 3 building less than two storeys in height to have a single exit if the area served is less than 200 m2, the travel distance does not exceed 25 m, and the occupant load is less than 60. Currently, the caster basement has only one exit.

4. **Provisions of the Building Code**

3.2.1.4. Floor Assembly over Basement

(1) A floor assembly immediately above a basement shall be constructed as a fire separation having a fire-resistance rating conforming to the requirements for floor assemblies in Articles 3.2.2.16. to 3.2.2.62., but not less than 45 min. (2) All loadbearing walls, columns and arches supporting a floor assembly immediately above a basement shall have a fire-resistance rating not less than that required in Sentence (1) for the floor assembly.

3.1.8.1. Fire Separations and Closures

(2) Openings in fire separations shall be protected with closures, shafts or other means in conformance with Articles 3.1.8.4. to 3.1.8.17. and with Subsections 3.1.9. and 3.2.8.

3.4.2.1. Minimum Number of Exits

(2) In buildings not more than 2 storeys in building height, a floor area is permitted to be served by one exit provided the floor area and the travel distance requirements conform to Table 3.4.2.A. and the total occupant load served by the exit is not more than 60.

5. **Applicant's Position**

The Applicant submitted that the building as constructed provides sufficiency of compliance with the relevant provisions of the OBC. With regard to the first dispute concerning the fire-resistance rating of the floor assemblies, including the supporting structures, the Applicant is of the opinion that hydraulic basements and oil cellars should be considered special structures under the OBC. Article 3.2.2.2. (Special and Unusual Structures) allows buildings that cannot be

classified under Articles 3.2.2.16. to 3.2.2.62 to be constructed in accordance with good fire protection engineering practice as found in the NFPA Fire Protection Handbook. As they feel that the oil cellar and caster basement are special structures which have been built in conformance with NFPA practices, the Applicant believes that these areas should be exempt from the Article 3.2.1.4.

Regarding the openings between the oil cellar and the caster basement and the floor level above them, the Applicant uses the same argument as in the previous issue. Because they feel that these two areas should be classified as special structures, again the OBC provisions concerning protection of openings is not applicable. Without changing the much of the design of the equipment central to the production of steel, it would be difficult to provide closures for all the openings between these lower areas and the floor above. They point out that the oil cellar is sprinklered. They also note that they have blocked some of the openings at issue through the installation of doors as per their "closure agreement" with the city.

Concerning the number of exits from the caster basement, the Applicant again relies on the argument that this space should be considered a special structure. As they point out, since liquid steel is being processed on the west side of the basement, the only available locations to which a fire-rated exit could be built is the existing unrated stairs found in the north and south portions of the east wall. Both stairs do not exit to the exterior but rather to the mill floor as access to exits which affords each set of stairs three separate exit routes. In their opinion, constructing fire-rated stairs that lead directly to the outside in the caster basement would congest the area and would possibly confuse workers and thereby make the situation more dangerous.

6. **Chief Building Official's Position**

The Respondent submitted that the Direct Strip Production Complex does not provide sufficiency of compliance with the aforementioned OBC provisions. They reject the Applicant's position that the oil cellar and caster basement should be viewed as special structures under OBC Article 3.2.2.2. The Respondent also indicated that it was not evident that a complete and adequate assessment of the entire facility according to the NFPA's good fire protection engineering practice had been carried out. Classifying the facility under Article 3.2.2.2. is not appropriate, they argue, since steel mills are specifically described under Article 3.2.2.59. Further, in their opinion, the sprinklering of the oil cellar only serves to alleviate the need for fire containment. It is not an adequate measure compensating the lack of appropriate fire-resistance rating for the subject floor assemblies, including protection of openings.

Regarding egress from the caster basement, the Respondent submitted that two exits must be provided in accordance with Sentence 3.4.2.1.(1). They feel that the exiting arrangement, as constructed, will considerably diminish the level of safety for the occupants on the caster basement level. They also believe the current travel distances are too far, and this heightens the potential danger.

7. **Commission Ruling**

It is the decision of Building Code Commission that the direct strip production complex provides sufficiency of compliance with Sentences 3.2.1.4.(1) & (2), Sentence 3.1.8.1.(2) and Sentence 3.4.2.5.(1) of the building code provided that:

i) the caster basement is sprinklered.

8. **Reasons**

i) The structural steel members supporting the first floor slab are very large in size and do not support the walls or roof assembly and the basement areas are sprinklered.

ii) The openings between the first floor and the main oil cellar and the caster basement are integral part of the process operation.

iii) The occupant load in the main oil cellar and the caster basement is low and only used for servicing as needed. The areas are similar to service spaces in many respects for exiting purposes.

iv) The building is ventilated to provide approximately 12 air changes/hour and would provide smoke venting in a fire emergency in excess of code standards.

v) An in-plant fire brigade with fire fighting equipment is the primary response in emergency. Training in fire safety and emergency evacuation is also provided for workers.

vi) A fire safety plan approved by the Chief Fire Official will be in place for this facility.

Dated at Toronto this 24th day in the month of September in the year 1997 for application number 1997-49.

RULING

1. **The Applicant**

   Mr. Harvey Fruitman, Executive Vice President, Torresdale Construction is a person to whom a building permit was issued under the Building Code Act, 1992 to renovate existing rental townhouse units into residential condominiums, at Countrylane Townhomes, Aurora, Ontario.

2. **Description of Construction**

   The Countryland Townhomes is a 38,707 m2 (9.565 acres) site, divided into twelve blocks, with a total of 200 rental townhouse units, consisting of 28,182 m2 (303,363.18 ft2) of building area.

   There are three types of townhouse suites; 100 A3 suites, 81 B3 suites, and 19 C3 suites. The approximate sizes of A3, B3 and C3 units are 145 m2 (1,558.32 ft2), 130 m2 (1,398.32 ft2) and 168 m2 (1,803.54 ft2) respectively. All suites are 3 storeys in building height.

The townhouse units are constructed of combustible construction. There are 2 parking spaces provided in the front of all A3 units at grade level. These parking spaces are intended for both the A3 suites as well as the adjoining B3 or C3 units, which are attached to the A3 units on the side opposite to the parking facilities. The subject parking areas are currently covered by a concrete deck and are separated by concrete block walls into garage-like car bays that can accommodate two vehicles. Both the A3 suites and the attached B3 or C3 units have an exit into this open-ended garage area. For the A3 units, this is the only exit currently provided.

The other unit types have an additional exit on their side of the building. The deck space above the parking area, which is attached to the second floor of the A3 suites, is currently used as a series of narrow patios which are abutted by a long, open-air corridor.

The proposed renovation would convert the townhouse units into residential condominiums. The work planned would divide the existing double car bays with 1 h fire separations into single vehicle garages which would also have steel overhead garage doors added to the openings to completely enclose the parking space. Drywall on the ceiling of all garages would be upgraded as well. The narrow patios and the long, external corridors would be replaced by larger patios that would cover the full concrete deck areas. It is proposed that pairs of A3 units share an exterior exit stair that would be accessible from the second storey patio area of both units. To maintain the continuity of the existing outside passageway for the exterior exit stairs, it is also proposed that bi-swinging gates be installed between the patios of the A3 units. This would allow the occupants of each A3 suite the option of choosing between several exit stairs in an emergency. The Applicant is also proposing to install hard-wired smoke detectors in all Countrylane Townhome units.

Countrylane Townhomes are classified as having a Group C - residential major occupancy. Many of the blocks and townhouse units are subject to Part 9 of the Building Code, however some portions of certain blocks exceed 600 m2 in building area and are therefore subject to Part 3.

3. **Dispute**

The issue at dispute between the Applicant and Respondent is whether the proposed renovations provide sufficiency of compliance with Sentences 3.2.5.5.(1), 3.2.5.6.(4) and Article 9.10.19.3., Articles 3.3.4.4. and 9.9.9.1., and Sentence 3.2.3.13.(2) and Article 9.9.4.4. of the Ontario Building Code. The partition of the double bays into single car garages and the placement of

garage doors at their openings blocks the only exterior exit door for the A3 suites. The proposed blocking of this exit creates three issues.

The first issue revolves around whether there is appropriate fire department access. Sentence 3.2.5.5.(1) requires that buildings over 600 m2 in building area provide access routes for fire department vehicles to the principle entrance and to each building face with required access openings. Sentence 3.2.5.4.(6) requires that a portion of a building that is cut off without access from the remainder of the building be not more than 45 m from fire fighting vehicle to the entrance of the remote area. Article 9.10.19.3. provides similar requirements for Part 9 buildings. It reiterates that access for fire fighting equipment shall be provided to each building by a street, private roadway or yard. The blocking of the A3 unit's parking level entrances has meant that the fire department access has been limited, and in the case of some buildings suites are farther than the permitted 45 m.

The second issue regarding the installation of the garage doors is the provision of a means of egress through the construction of a new second storey, shared exterior stairs proposed for the A3 units. Articles 3.3.4.4. and 9.9.9.1. of the OBC set out the egress standards from a dwelling unit in Part 3 and Part 9 buildings respectively. In particular, Article 3.3.4.4 requires that an egress door be provided on the uppermost and lowest storey of a dwelling unit unless certain conditions are met. As well, the "stacked" nature of the townhouses may not satisfy Sentence 9.9.9.1.(2), which requires that the travel distance be not more than one storey if there is no dwelling unit above or below. The proposed exit doorways are also higher than the 1.5 m allowed in both Articles 3.3.4.4. and 9.9.9.1. Also in dispute is Sentence 3.3.4.4.(2) which requires that a dwelling unit's exit door shall open directly into a public access to an exit. The proposal to replace the long corridors fronting the narrow patios with enlarged, connected patios may not be consistent with a public access to an exit.

The third issue is that the proposed new shared exterior egress stairs pass within roughly 1 m of the garage door openings and may result in dangerous exposure to a fire originating in a garage. Sentence 3.2.3.13.(2) requires that openings in the exterior wall of a building located within 3 m horizontally of an unenclosed stair serving that building which may cause a hazard to such stairs shall be protected with wired glass or glass block. Article 9.9.4.4. provides the same standards for Part 9 buildings.

4. **Provisions of the Building Code**

Sentence 3.2.5.5.(1) Access Routes

(1) Every building which is more than 3 storeys in building height or more than 600 m2 (6460 ft2) in building area shall be provided with access routes for fire department vehicles

(a) to the principal entrance, and
(b) to each building face having access openings for fire fighting as required in Articles 3.2.5.1. and 3.2.5.2.

Sentence 3.2.5.6.(4) Location of Access Routes

(4) Where a portion of a building is completely cut off from the remainder of the building so that there is no access to the remainder of the building, the access routes required by Sentence (2) shall be located so that the unobstructed path of travel from the vehicle to one entrance of each such portion is not more than 45 m (147 ft 8 in).

Article 9.10.19.3 Fire Department Access to Buildings

(1) Access for fire department equipment shall be provided to each building by means of a street, private roadway or yard.

(2) Where access to a building as required in Sentence (1) is provided by means of a roadway or yard, the design and location of such roadway or yard shall take into account connection with public thoroughfares, weight of fire fighting equipment, width of roadway, radius of curves, overhead clearance, location of fire hydrants, location of fire department connections and vehicular parking.

Article 3.3.4.4. Egress from Dwelling Units

(1) Single storey dwelling units in apartment buildings need not lead to a public corridor or exterior passageway on the same storey provided the dwelling units are served by private stairways leading directly to a public access to exit on the storey

(a) immediately above, and (b) immediately below. (2) Except as provided in Sentences (3) and (4), every dwelling unit containing more than 1 storey shall have an exit door or an egress door opening directly into a public access to exit from the uppermost storey and from the lowest storey of the dwelling unit so that the floor level of each such storey is served by an exit or egress door located not more than 1.5 m (4 ft 11 in) above or below the floor level.

(3) A single exit is permitted from a dwelling unit provided the exit is an exterior doorway not more than 1.5 m (4 ft 11in) above adjacent ground level and (a) it is not necessary to travel up or down more than 1 storey to reach the exit door, or (b) the uppermost floor level opens to a balcony not more than 6 m (19 ft 8 in) above adjacent ground level.

(4) An a egress door from either the uppermost storey or the lowest storey in a dwelling unit, as required in Sentence (2), need not be provided

(a) where that storey is served by a stairway that

(i) leads to a public access to exit,

(ii) has not direct access to any other storey in the dwelling unit, and

(iii) is separated from the other storeys in the dwelling unit by a fire separation having a fire-resistance rating of not less than 45 min, or

(b) where a smoke alarm conforming to Article 3.2.4.21. is installed

(i) on the uppermost storey of a dwelling unit having not more than 2 storeys above the first storey of the building, or

(ii) on each storey of the dwelling unit provided it is not necessary to travel either more than 18 m (59 ft 1 in), or more than 1 storey up or down to reach the egress door.

(5) In buildings of residential occupancy not more than 3 storeys in building height, a doorway from a dwelling unit is permitted to open directly into an exit stairway provided such dwelling unit has a second and separate means of egress.

(6) A doorway from a dwelling unit may open onto an interior corridor served by a single exit, or an exterior balcony served by a single exit stairway, or an exterior passageway served by a single exit stairway provided each dwelling unit has a second and separate means of egress.

Article 9.9.9.1 Travel Limit to Exits or Egress Doors

(1) Except as provided in Sentences (2) and (3), every dwelling unit containing more than one storey shall have a sufficient number of exits of egress doors so that it shall not be necessary to travel up or down more than 1 storey to reach a level served by

(a) an egress door to a public corridor, enclosed exit stair or exterior passageway, or (b) an exit doorway not more than 1.5 m (4 ft 11 in) above adjacent ground level. Sentence 3.2.3.13.(2) Protection of Exit Facilities (2) Where an unenclosed exterior exit stair or ramp may be exposed to fire from openings in the exterior walls of the building it serves, the openings in the exterior walls of the building shall be protected with wired glass in fixed steel frames or glass block conforming to Article 3.1.8.14. where the openings in the exterior walls of the building are within 3 m (9 ft 10 in) horizontally and

(a) less than 10 m (32 ft 10 in) below the exit stair or ramp, or (b) less than 5 m (16 ft 5 in) above the exit stair or ramp. Article 9.9.4.4. Openings Near Unenclosed Exit Stairs and Ramps.

Where an unenclosed exterior exit stair or ramp provides the only means of egress from a suite, and is exposed to fire from openings in the exterior walls of another fire compartment, the openings in the exterior walls of the building shall be protected with wired glass in fixed steel frames or glass block conforming to Articles 9.10.13.5. and 9.10.13.7. when the openings in the exterior walls of the building are within 3 m (9 ft 10 in) horizontal

5. **Applicant's Position** The Applicant submitted that the proposed renovations provide sufficiency of compliance with the above listed provisions. Regarding the issue of fire department access, for the Part 3 buildings they recognize that the 45 m limit between the entrance of a cutoff unit and a fire department vehicle may not be met. Instead, they rely on Sentence 11.3.5.1.(1). This provision deals with extended buildings and it would allow them to utilize compliance alternative C22.

   This alternative states that for "buildings 6 storeys and less, existing access to existing occupancy is acceptable..." This would permit the Applicant to close over the garage entrances and construct new exit stairs without providing additional measures to compensate for the lesser access. Considering the Part 9 buildings under the same extended buildings provision, the Applicants propose to employ compliance alternative C153 to the same effect. In their view, the extended buildings meet the intent of the OBC, and roughly 90 per cent of the units meet the literal requirements of the Code.

   Since the issue of providing an exit from the A3 suites requires the construction of new exterior exit stairs, the Applicant relies not upon compliance alternatives but new construction provisions in Parts 3 and 9. To address the requirement of providing an exit from the uppermost and lowest floors of the unit found in Sentence 3.3.4.4.(2), the Applicants propose to install a hard-wired 120 volt interconnected smoke alarm on each floor of all dwelling units as per Subclause

3.3.4.4.(4)(b)(i). In their view, this would preclude the necessity for uppermost and lowest floor exits.

For the Part 9 buildings, they argue that egress could be accommodated under Clause 9.9.9.1.(1)(b) or Sentence 9.9.9.1.(2). The first provision allows dwelling units with more than 1 storey to have a sufficient number exits so that it is not necessary to travel up or down more than 1 storey to reach a level served by an exit doorway that is not more than 1.5 m (4 ft 11 in) above the adjacent ground. (The Applicant does admit however that the proposed second level exit door is higher than 1.5 m. This issue is not addressed.) The Applicant also notes that Sentence 9.9.9.1.(2) allows travel distance to be greater than 1 storey if the floor level is served by openable windows. This should afford them some greater flexibility in interpreting the exiting arrangements they have provided. Further, these units will also have the interconnected, hard-wired smoke alarm system.

Concerning the issue of the door opening into an access to exit as required under 3.3.4.4.(2), the Applicants argue that having two dwelling units share an exit stair to the ground level is similar to many exiting arrangements in older buildings. They also argue that the continuity of the exterior passageway will be maintained due to the bi-swinging gates that are proposed to be installed between the patios. This continuity of the passageway will give occupants access to two or more exterior exit stairs. Overall, it is their opinion that the exiting as designed meets the intent of the Code.

The Applicants believe that they have addressed the issue of exposure to the exterior stair as well. They note that the new exiting arrangements would offer occupants many escape options in an emergency, thereby avoiding stairs that may present hazards. The garages will be divided with 1 h fire separations and will have upgraded drywall on the ceilings. The new garage doors, they argue, will also offer some protection. Lastly, they point to the concrete block fire separations between the units and the proposed smoke alarm system which they feel will give the entire site a good level of fire protection.

6. **Chief Building Official's Position**

The Respondent submitted that the proposed renovations did not provide sufficiency of compliance with the provisions discussed and in some instances place the buildings into situations of non-compliance. They reject compliance alternatives C22 and C153 which depends on maintaining the existing access because, in their view, the proposed addition of garage doors blocks off the existing access. While adding garage doors may be deemed to be "extending the

building", the Respondent argues however that this particular extension substantially changes the existing access that the alternative allows as acceptable.

The municipality believes that the exiting requirements have not been satisfied. For the Part 3 buildings, they hold that the proposed second floor door does not open into an access to an exit. In their opinion, the linked patios do not constitute an access to an exit, nor a passageway. In fact, they are concerned that the balconies may support potential obstacles for exiting such as bar-be-ques, furniture and other accessories. In the Part 9 structures the Respondent does not believe that travel distances allowed in Sentence 9.9.9.1.(2) due to openable windows can be considered legitimate due to their contention that as stacked townhouses there are dwelling units above and below other units.

The Respondent also argues that the stairs do not meet the provisions regarding exposure to exterior exit stairs. The creation of the external stairs only serves to add to the non-compliance of the townhouse suites. The result of this proposal would be a reduction in safety due to potential fire exposure. They also feel that the stairs, as external exits, present dangers during inclement weather such as wind, rain and ice. This would be especially an issue for visitors unfamiliar with the stairs and who will often not be able to use the garage entrance.

7. **Commission Ruling**

It is the decision of the Building Code Commission that the proposed renovations provide sufficiency of compliance with Sentence 9.9.9.1.(1), Articles 3.3.4.4., 9.10.19.3. and Subsection 3.2.5.

8. **Reasons**

i) Additional exterior stairways will be provided to improve fire department access and exiting from the 3A dwelling units.

ii) Hard-wired smoke alarms will be provided on every level and interconnected within each dwelling unit.

iii) Garages within each dwelling unit will be separated from each other by construction having a 1 hour fire resistance rating.

iv) Occupant safety is not reduced consistent with the intent of Part 11 of the code.

RULING

1. **The Applicant**

   Mr. Robert Riddell, Senior Technical Specialist, Algoma Steel Inc, is a person who has been issued an order to comply under the Building Code Act, 1992 to bring the floor assemblies over the oil cellar and the caster basement of a recent addition in conformity with certain provisions of the Ontario Building Code at the Direct Strip Production Complex, Algoma Steel Inc., 105 West Street, Sault Ste. Marie, Ontario.

2. **Description of Construction**

The existing building is a three and four storey industrial structure with an area of approximately 60,380 m2 (650,000 ft2). The addition, constructed between 1996 and 1997, has added another 32,520 m2 (350,000 ft2) to the structure making the current total building area 92,900 m2 (1,000,000 ft2).

The building is constructed of noncombustible construction. It is equipped with a fire alarm system. The building also has a partial sprinkler system, only in the oil cellar of the addition. It does not have a standpipe and hose system.

Within the addition there are two large depressed areas in the main floor. These areas are known as the oil cellar and the caster basement. They are located beneath the addition's major production and processing equipment and are used for servicing the machinery above and the accommodation of ancillary equipment. The floor assemblies above the oil cellar and caster basement are concrete slab supported with unprotected steel beams.

Both the existing building and the addition are considered to have a Group F, Division 3 (low hazard industrial) major occupancy. The structure, including the addition, is used to manufacture steel slabs.

3. **Dispute**

There are three issues at dispute between the Applicant and the Respondent. The first is whether the floor assemblies above the oil cellar and the caster basement provide sufficiency of compliance with Sentences 3.2.1.4.(1) and (2). These provisions of the OBC require that a floor assembly above a basement must be constructed as a fire separation with a fire-resistance rating as determined in Subsection 3.2.2., but not less than 45 min. The supporting elements supporting the subject floor assembly are required to have the same fire-resistance rating as the floor. While the concrete slab floor above the oil cellar and caster basement in the Direct Strip Production Complex may provide the necessary 45 minute rating, the steel supporting beams for these floor assemblies are unprotected and therefore do not have a resistance rating.

The second dispute is whether the openings in the said floor assemblies provide sufficiency of compliance with OBC Sentence 3.1.8.1.(2), which requires that all openings in fire separations must be protected with closures. The openings at the oil cellar and the caster basement do not have closures. There are large numbers of pipes that access the mill stands, and in so doing create many openings between floor levels. As well, the steel production equipment in some

areas of the complex forms part of the floor, and as it moves it periodically exposes the basement.

The last dispute is over whether the number of exits from the caster basement of the Direct Strip Production Complex provide sufficiency of compliance with Sentence 3.4.2.1.(2) of the Code. This provision allows a floor area in a Group F, Division 3 building less than two storeys in height to have a single exit if the area served is less than 200 m2, the travel distance does not exceed 25 m, and the occupant load is less than 60. Currently, the caster basement has only one exit.

4. **Provisions of the Building Code**

3.2.1.4. Floor Assembly over Basement

(1) A floor assembly immediately above a basement shall be constructed as a fire separation having a fire-resistance rating conforming to the requirements for floor assemblies in Articles 3.2.2.16. to 3.2.2.62., but not less than 45 min. (2) All loadbearing walls, columns and arches supporting a floor assembly immediately above a basement shall have a fire-resistance rating not less than that required in Sentence (1) for the floor assembly.

3.1.8.1. Fire Separations and Closures

(2) Openings in fire separations shall be protected with closures, shafts or other means in conformance with Articles 3.1.8.4. to 3.1.8.17. and with Subsections 3.1.9. and 3.2.8.

3.4.2.1. Minimum Number of Exits

(2) In buildings not more than 2 storeys in building height, a floor area is permitted to be served by one exit provided the floor area and the travel distance requirements conform to Table 3.4.2.A. and the total occupant load served by the exit is not more than 60.

5. **Applicant's Position**

The Applicant submitted that the building as constructed provides sufficiency of compliance with the relevant provisions of the OBC. With regard to the first dispute concerning the fire-resistance rating of the floor assemblies, including the supporting structures, the Applicant is of the opinion that hydraulic basements and oil cellars should be considered special structures under the OBC. Article 3.2.2.2. (Special and Unusual Structures) allows buildings that cannot be

classified under Articles 3.2.2.16. to 3.2.2.62 to be constructed in accordance with good fire protection engineering practice as found in the NFPA Fire Protection Handbook. As they feel that the oil cellar and caster basement are special structures which have been built in conformance with NFPA practices, the Applicant believes that these areas should be exempt from the Article 3.2.1.4.

Regarding the openings between the oil cellar and the caster basement and the floor level above them, the Applicant uses the same argument as in the previous issue. Because they feel that these two areas should be classified as special structures, again the OBC provisions concerning protection of openings is not applicable. Without changing the much of the design of the equipment central to the production of steel, it would be difficult to provide closures for all the openings between these lower areas and the floor above. They point out that the oil cellar is sprinklered. They also note that they have blocked some of the openings at issue through the installation of doors as per their "closure agreement" with the city.

Concerning the number of exits from the caster basement, the Applicant again relies on the argument that this space should be considered a special structure. As they point out, since liquid steel is being processed on the west side of the basement, the only available locations to which a fire-rated exit could be built is the existing unrated stairs found in the north and south portions of the east wall. Both stairs do not exit to the exterior but rather to the mill floor as access to exits which affords each set of stairs three separate exit routes. In their opinion, constructing fire-rated stairs that lead directly to the outside in the caster basement would congest the area and would possibly confuse workers and thereby make the situation more dangerous.

6. **Chief Building Official's Position**

The Respondent submitted that the Direct Strip Production Complex does not provide sufficiency of compliance with the aforementioned OBC provisions. They reject the Applicant's position that the oil cellar and caster basement should be viewed as special structures under OBC Article 3.2.2.2. The Respondent also indicated that it was not evident that a complete and adequate assessment of the entire facility according to the NFPA's good fire protection engineering practice had been carried out. Classifying the facility under Article 3.2.2.2. is not appropriate, they argue, since steel mills are specifically described under Article 3.2.2.59. Further, in their opinion, the sprinklering of the oil cellar only serves to alleviate the need for fire containment. It is not an adequate measure compensating the lack of appropriate fire-resistance rating for the subject floor assemblies, including protection of openings.

Regarding egress from the caster basement, the Respondent submitted that two exits must be provided in accordance with Sentence 3.4.2.1.(1). They feel that the exiting arrangement, as constructed, will considerably diminish the level of safety for the occupants on the caster basement level. They also believe the current travel distances are too far, and this heightens the potential danger.

7. **Commission Ruling**

It is the decision of Building Code Commission that the direct strip production complex provides sufficiency of compliance with Sentences 3.2.1.4.(1) & (2), Sentence 3.1.8.1.(2) and Sentence 3.4.2.5.(1) of the building code provided that:

i) the caster basement is sprinklered.

8. **Reasons**

i) The structural steel members supporting the first floor slab are very large in size and do not support the walls or roof assembly and the basement areas are sprinklered.

ii) The openings between the first floor and the main oil cellar and the caster basement are integral part of the process operation.

iii) The occupant load in the main oil cellar and the caster basement is low and only used for servicing as needed. The areas are similar to service spaces in many respects for exiting purposes.

iv) The building is ventilated to provide approximately 12 air changes/hour and would provide smoke venting in a fire emergency in excess of code standards.

v) An in-plant fire brigade with fire fighting equipment is the primary response in emergency. Training in fire safety and emergency evacuation is also provided for workers.

vi) A fire safety plan approved by the Chief Fire Official will be in place for this facility.

Dated at Toronto this 24th day in the month of September in the year 1997 for application number 1997-49.

BCC Ruling No. 97-42-584

BUILDING CODE COMMISSION DECISION ON B.C.C. #97-42-584

IN THE MATTER OF Subsection 24 (1) of the *Building Code Act, 1992*. AND IN THE MATTER OF Article 9.8.8.5. of "the Building Code" (Ontario

Regulation 419/89 as amended by Ont. Reg. 183/88, 581/88, 11/89 and 115/89).

AND IN THE MATTER OF an application by Ms. Gail Fischer-Taylor and Mr. Burns Wattie, Homeowners, 47 Poplar Plains Road, Toronto, Ontario, for the resolution of a dispute with Ms. Pamela Coburn, Chief Building Official, City of Toronto, Ontario, concerning whether the wood guard for the proposed third floor deck provides sufficiency of compliance with Article 9.8.8.5. of the Ontario Building Code at 47 Poplar Plains Road, Toronto, Ontario.

Mr. Tim Scott
Principal
Natale and Scott Architects
Agent for the Applicant

RULING

1. **The Applicants**

   Ms. Gail Fischer-Taylor and Mr. Burns Wattie are person who were issued a building permit under the *Building Code Act, 1992* to renovate the third floor of their existing residence at 47 Poplar Plains Road, Toronto, Ontario.

2. **Description of Construction** The Applicant's building is described as a semi-detached structure, with a Group C - Residential occupancy. It has a gross floor area of 332.7 m2 (2,581 ft2) and has a building height of three storeys.

   The Applicants recently renovated their house. The work included demolishing a two-storey rear porch, substantial interior renovations of the second and third floors, upgrading windows and doors, adding a new basement entrance, and rebuilding an existing third floor deck.

   The guard around the deck was replaced with a new one that was constructed with 3/4 in. x 1 in. horizontal wood slats, spaced at 1.5 in. on centre. The height of the guard is 1,524 mm (5 ft. 0 in.).

3. **Dispute**

   The issue at dispute between the Applicant and the Respondent is whether the new guard with horizontal wood slats that was built around the third floor deck provides sufficiency of

compliance with Article 9.8.8.5. of the OBC. This provision requires that guards built around balconies, porches and decks be designed so as not to facilitate climbing of the guard.

4. **Provisions of the Building Code**

9.8.8.5. Designs to Prevent Climbing.

Guards around exterior balconies, porches, and decks of buildings of residential occupancy shall be designed so that no member, attachment or opening located between 100 mm (4 in) and 900 mm (2 ft 11 in) above the floor of the balcony, porch or deck will facilitate climbing.

5. **Applicant's Position**

The Applicant submitted that the guard, as designed and constructed, provides sufficiency of compliance with Article 9.8.8.5. In their opinion, the spacing of the slats, with only a 3/4 in. gap between them means that it would not be possible for anyone to gain a foot or handhold.

6. **Chief Building Official's Position**

The Respondent submitted that the guard does not provide sufficiency of compliance because, in their view, the spaces between the slats do facilitate climbing by a child. The City's concern is that the guard's design presents real danger for a serious accident to occur. As they have jurisdiction for enforcement of the building code, they believe that the guard, which they have inspected on several occasions, leaves them open to liability.

7. **Commission Ruling**

It is the decision of the Building Code Commission that the wood guard for the 3rd floor deck does not provide sufficiency of compliance with Article 9.8.8.5. of the Building Code.

8. **Reasons**

i) The guard is required to be altered between 100mm to 900 mm and this can be achieved easily without altering the current design significantly to eliminate the possibility of climbing.

RULING

1. **The Applicant**

   Mr. David Bryer is a person who has applied for a building permit under the Building Code Act, 1992 to construct an addition to the Gunn Metal Stamping plant at 32 Airpark Place, Guelph, Ontario.

2. **Description of Construction**

   The existing building is a single storey manufacturing plant that was constructed in 1989 and is used for metal stamping. It is described as having a Group F, Division 3, low hazard industrial occupancy. The structure is composed of combustible and noncombustible construction. It is not equipped with a sprinkler system, fire alarm system, nor a standpipe and hose system. The area of the existing building is calculated at 1,482.4 m2, or 1,604.8 m2 including the 122.4 m2 waste bin storage area that was constructed in 1996 and is located to the west or rear of the structure.

   The proposed one storey addition would add 1,514.7 m2 to the north building face in order that the metal stamping activities may expand.

3. **Dispute**

The issue at dispute between the Applicant and the Respondent is whether the proposed addition should be equipped with a standpipe and hose system as required under OBC Article 3.2.9.1. The origins of the dispute are found in differing calculations of the area of the existing building. The three-sided, waste bin storage area was not considered as part of the building area by the Applicant. The Respondent, on the other hand, included the subject waste bin enclosure as existing building area.

4. **Provisions of the Building Code**

3.2.9.1. (Standpipe and Hose Systems) Where Required

(1) Except as provided in Article 3.2.9.2., a standpipe and hose system shall be installed in every building that (a) is more than (i) 3 storeys in building height, or (ii) 14 m (45 ft 11 in) in height measured between grade and the ceiling of the uppermost storey, (b) is greater in building area than the area shown in Table 3.2.9.A. for the applicable building height shown in the Table where the building (i) is not sprinklered, and (ii) is not more than 14 m (45 m 11 in) high measured between grade and the ceiling of the top storey, or(c) contains more than one storey below grade.

5. **Applicant's Position**

The Applicant submitted that a standpipe and hose system is not required since the total building area of the enlarged structure would only be 2,996.1 m2. It was their intention was to limit the size of the proposed addition so that the total floor area would be less than the 3,000 m2 threshold, over which a standpipe and hose system would be necessary.

In their view the waste bin storage area constructed in 1996 should not be used when calculating the building's area. They argue that the space is uninhabited and was built simply to lessen the water contamination in the waste bins and to provide a visual screen. They point out that the entire west face of the waste bin storage area is open, while the south exposure has a large opening as well.

The Applicant contends that the comprehensive definition of building within in the Building Code Act (BCA) is too onerous when considering the application of Article 3.2.9.1. and the requirements for standpipe and hose systems. They believe that a fairer definition to use in this

circumstance is building area, which is found in Article 1.1.3.2. of the OBC. This latter definition refers to exterior walls as a benchmark for calculating area. Without any wall on the west exposure of the waste bin area, the Applicant's position is that this space does not meet the definition of a building and should therefore not be considered as part of the building area.

6. **Chief Building Official's Position**

The Respondent submitted that the total area of the expanded plant would be 3,119.5 m2 and that a standpipe and hose system should be installed in the proposed addition in accordance with Article 3.2.9.1. In their view the waste bin storage area should be considered in the building area calculations.

The municipality relied upon the definition found in the BCA, which states that a building is "a structure occupying an area greater than ten square metres consisting of a wall, roof and floor or any of them...". According to this definition, the waste bin space would clearly qualify as a building and thus should be counted in the building area.

They were prepared, however, to consider the waste bin area as an exterior canopy if the Applicant removed all the wall panels.

7. **Commission Ruling**

It is the decision of the Building Code Commission that the addition without a standpipe and hose system provides sufficiency of compliance with Article 3.2.9.1. of the Ontario Building Code.

8. **Reasons**

i) The total building area excluding the bin shelter which is considered an ancillary structure is less than 3000 m2 and is fully open on one side and partially open on a second side.

ii) The shelter is separated from the main building by a metal clad insulated 10 inch block wall and an insulated steel door.

iii) Access to the shelter for fire fighting purposes is provided directly from the exterior.

The Applicant

Mr. Anthony Krimmer
Chief Building Official
City of Waterloo
The Respondent

RULING

1. **The Applicant**

   Mr. Jeff Zavitz is a person who was issued a building permit under the *Building Code Act, 1992* to construct a three storey, mixed-use structure at 10 Regina Street North, Waterloo, Ontario.

2. **Description of Construction**

   The Applicant intends to construct a three storey, mixed-use building. The proposal indicates that the first floor is to be commercial space and the second and third floors are to be a mix of two, two-storey residential apartment units and one, two-storey Class D office unit located at the south end of the building. The building is described as having multiple occupancies; Group C - residential, Group D - business and personal services, and Group E - mercantile.

   The structure will be composed of combustible construction and has an area of approximately 600 m2 (6,100 ft2). The building will contain with a fire alarm system. It will not be equipped with a sprinkler system.

3. **Dispute** The issue at dispute between the Applicant and Respondent is whether the proposed third floor office space provides sufficiency of compliance with Article 9.9.8.2. of the OBC. This provision requires that Group D occupancies provide not less than two exits from each floor.

The single, two-storey office unit located on the second and third floor of the proposed building has an internal stair between floors, but provides no other stairs. The second floor of this unit is not in dispute since Sentence 9.9.8.2.(2) allows one and two storey buildings to have only one exit where the floor areas, travel distances and occupant loads conform. This provision does not apply to the third floor of the commercial unit. A second exit is required.

4. **Provisions of the Building Code**

9.9.8.2. Number of Required Exits

(1) Except as provided in Sentences (2) and (3) and Subsection 9.9.9., not less than 2 exits shall be provided from every floor area, spaced so that the travel distance to the nearest exit is not more than (a) 40 m (131 ft 3 in) in the case of business and personal services occupancies, (b) 45 m (147 ft 3 in) for all occupancies where the floor area is sprinklered, and (c) 30 m (98 ft 5 in) for all other occupancies. (2) Except as provided in Subsection 9.9.9., a single exit is permitted from each storey in buildings of 1 and 2 storeys in building height provided the floor are and travel distance requirements conform to those required in Article 9.9.7.3. and the total occupant load served by an exit facility does not exceed 60 persons.

5. **Applicant's Position**

The Applicant submitted that while the third floor office unit is not served with a second exit, they believe that the measures they have included provide an increased level of safety that creates sufficiency of compliance with Sentence 9.9.8.2.(1). The chief measure being provided by the Applicant is an interconnected fire alarm system between all units in the building. As well, the stair connecting the second and third floors is 1.1 m (44 in) wide.

The Applicant also notes that Article 9.9.8.2. allows the travel distance to the nearest exit to be up to 40 m in a Group D occupancy. The travel distance from the third floor to the fire-separated, exit stair on the second floor in the subject office space is only 18 m. Further, the occupant load will only be five persons.

The Applicant also makes a comparison with the requirements of Article 9.9.9.1. They point out that the adjacent residential apartment units do not have to provide a second exit. They argue that if Article 9.9.9.1. allows residents, who may be sleeping, in a residential unit to travel down one storey to reach an exit stair, then the same standard could be applied to a low occupancy office unit that operates only during daytime hours.

Sentence (2) of Article 9.9.9.1. further allows that the travel limit from a floor level in a dwelling unit to an exit door may exceed one storey where that floor has an openable window of certain dimensions and a sill not higher than 1 m from the floor and not higher than 7 m from the ground level outside. In the case of the subject office unit, the Applicant notes that the second floor is served by both a french balcony 4 m above the ground level and the fire-separated exit stair.

6. **Chief Building Official's Position**

The Respondent submitted that the third storey, Group D occupancy, with a floor area of 54 m2 is required to have 2 exits in accordance with Sentence 9.9.8.2.(1).

They also submitted that they did not have the jurisdiction to approve the Applicant's measures to provide sufficiency of compliance.

7. **Commission Ruling**

It is the decision of the Building Code Commission that the third floor office space provides sufficiency of compliance with Article 9.9.8.2. of the Ontario Building Code provided that interconnected smoke alarms are installed at each floor level within the two storey office suite near the connecting stair in conformance with Subsection 9.10.18.

8. **Reasons**

i) The size of the 2 storey suite is small (approximately 60 m2) per floor level and the occupant load is low.

ii) The suite is separated from the remainder of the building by a fire separation having a 3/4 hour fire resistance rating.

iii) The travel distance from any point in a suite to an exterior exit door is approximately 18 m.

iv) Additional interconnected smoke detection is provided in the suite.

v) It is the opinion of the Building Code Commission that the two storey suite exit does provides a lesser risk to the occupants of the "D" occupancy than a dwelling unit in a residential occupancy of a similar configuration which would comply with the Ontario Building Code.

RULING

1. **The Applicant**

   Mr. Jonathan Dej and Mrs. Donna Dej are persons who applied for a building permit under the *Building Code Act, 1992* to reconfigure their water and sewer services at 844 Stirling Avenue South, Kitchener, Ontario.

2. **Description of Construction**

   The subject building, located at 844 Stirling Avenue South in Kitchener, is a one storey, semi-detached structure. The building is described as having a Group C - residential occupancy. It has a building area of approximately 700 ft2. It is composed of combustible construction. The adjoining building has a similar description. It is located at 846 Stirling Avenue South. Both dwellings were built in 1948.

   The existing water and sewage services at 844 Stirling Avenue South runs from the municipal mains directly into the subject building at the basement level, where both services divert into

two, with one set serving 844 Stirling Avenue South while the other set travels through the party wall and serves 846 Stirling Avenue South.

The Applicant proposes to alter this existing configuration so that the new diversion point of both services to the adjacent property would be in front of and external to 844 Stirling Avenue South. They also propose to cap both existing water and sewage services to 846 Stirling Avenue South within their dwelling.

3. **Dispute**

The issue at dispute between the Applicant and Respondent is whether the proposed water and sewage service connection provide sufficiency of compliance with Sentence 7.1.6.4.(1) of the OBC. This provision requires that piping in a building must connect to the public mains separately from that of another building.

4. **Provisions of the Building Code**

Sentence 7.1.6.4. Separate Services (1) Piping in any building shall be connected to the public services separately from piping of any other building, except that an ancillary building on the same property may be served by the same service.

5. **Applicant's Position**

The Applicant submitted that the proposed new water and sewage configuration, in which the diversion of services to the adjacent property would be located in front and external to their dwelling, provides sufficiency of compliance with Sentence 7.1.6.4.(1). While not creating separate services for both properties, the proposal does eliminate the need to have the piping for 846 Stirling Avenue South running through the Applicant's building.

As a mitigating measure the Applicants are prepared to offer an easement over a portion of their front yard that would allow the owners of the adjacent property to install separate services external to their house.

6. **Chief Building Official's Position**

The Respondent submitted that the proposed water and sewer configuration does not provide sufficiency of compliance with Sentence 7.1.6.4.(1). They contend that the proposed connection is not separate from that of the adjacent property.

7. **Commission Ruling**

It is the decision of the Building Code Commission that the proposed water and sewage service connections provide sufficiency of compliance with Sentence 7.1.6.4.(1) of the Ontario Building Code at 844 Stirling Avenue South, provided that an easement registered on title is available for access to the service connections by 846 Stirling Avenue South.

8. **Reasons:**

i) The external connections provide better access for maintenance to both properties.
ii) No additional loads are being added to the system.
iii) Both parties at 844 and 846 consent to this application.

Dated at Toronto this 11th day in the month of September in the year 1997 for application number 1997-44.

City of St. Thomas
The Respondent

RULING

1. **The Applicant**

   Mr. Clare Kielstra is a person to whom an order was issued under the *Building Code Act, 1992* to bring a recently constructed addition to an existing dwelling into compliance with the Ontario Building Code at 12 Spruce Street, St. Thomas, Ontario.

2. **Description of Construction**

   The renovation at dispute is a 78 ft2 addition on the east side of an existing dwelling at 12 Spruce Street, St. Thomas, Ontario. The existing building is described as a 1 and a half storey, 1,100 ft2 structure. Both the existing building and the addition are combustible construction. The building is classified as having a Group C - residential occupancy.

   The east-facing exposure of the addition is located 1.23 m (4 ft) from the adjacent property line. This exposing building face contains a window which is calculated to be an unprotected opening of approximately 35 per cent.

3. **Dispute**

   The issue at dispute between the Applicant and Respondent is whether the subject window provides sufficiency of compliance with Sentence 9.10.14.1.(1) of the Building Code. This provision of the OBC, specifically Table 9.10.14.A., requires that an exposing building face with a limiting distance of 1.23 m (4 ft) have a total of 7 per cent unprotected opening or less. As

mentioned, the subject wall has an unprotected opening of 35 per cent. In terms of actual area permissible for this exposing building face as an unprotected opening, the 7 per cent maximum found Table 9.10.14.A. translates into 5.6 ft2. The existing unprotected opening is measured at 38.5 ft2.

4. **Provisions of the Building Code**

9.10.14.1.(1) Maximum Percentage of Unprotected Openings

Except as provided in Sentence (2) and in Articles 9.10.14.3. to 9.10.14.11., the maximum percentage of unprotected openings in an exposing building face shall conform to Table 9.10.14.A. or to Subsection 3.2.3., whichever is the least restrictive for the occupancy being considered.

5. **Applicant's Position**

The Applicant, Mr. Kielstra, was the contractor for the subject renovation. He submitted that while the opening clearly exceeds the allowable limit, it would have been helpful to him if one of the earlier inspections done during construction had revealed this deficiency. Instead, it was only on the final inspection that the city brought this issue to his attention.

The Applicant's clients wish to retain the opening. Installing a fire shutter above the window was deemed by his clients not to be consistent with the design. Accordingly, the Applicant is proposing other options, including installing a single sprinkler in the addition and/or a 45 minute fire-rated door between the existing and new portions of the dwelling.

The Applicant also submitted that the addition is used as a foyer. Furthermore, the town's fire department can provide response within 3-4 minutes.

6. **Chief Building Official's Position**

The Respondent submitted that the maximum allowable unprotected opening for the subject exposing building face is 7 per cent, as described in Table 9.10.14.A. Further, they indicated that the Building Code does not contain provisions that would allow them to accept the proposals offered by the Applicant. The Respondent noted that by installing a sprinkler system in the addition, and/or the 45 minute fire-rated closure, sufficiency of compliance could be achieved.

7. **Commission Ruling**

It is the decision of the Building Code Commission that the proposed unprotected openings provide sufficiency of compliance with Sentence 9.10.14.1.(1) of the Building Code provided:

i) The addition is sprinklered and the sprinkler head is the quick response type.

ii) That a smoke alarm is installed in the addition and in the building in accordance with Article 9.10.18.1. of the Building Code.

8. **Reasons:**

i) The addition is small and is sprinklered.

ii) If the complete building face were considered at the line of the addition as exposed building face, the percentage of unprotected openings would be significantly less.

iii) Evidence provided indicated that the Fire Department response time is good and the fuel load within the addition is limited.

iv) The addition of smoke alarms provides early warning for occupants.

v) It is the opinion of the Building Code Commission that the addition does not create a hazard to the property considering the additional protection provided.

For the Respondent

RULING

1. **The Applicant**

   Ms. Elizabeth Peck is a person to whom an order was issued under the Building Code Act, 1992 to bring the stairs in their residence into compliance with Sentence 9.8.5.3.(1) of the Ontario Building Code at Cowper Island, #B-424, 42R6075, Pt 1, Township of the Archipelago, Ontario.

2. **Description of Construction**

   The Applicants recently constructed a two storey, pre-manufactured, log building. Including balcony, the structure has a total of 1,394 ft2. The building is described as a Group C - residential occupancy.

   The stairs between the ground and second floor in the subject building contain a 90 degree, right angle turn turn. The stairs, as built, have a total of six winders, each covering 15 degrees.

3. **Dispute**

   The issue at dispute between the Applicant and Respondent is whether the subject stairs provide sufficiency of compliance with Sentence 9.8.5.3.(1) of the Ontario Building Code. This sentence

requires that winders within dwelling units turn through an angle of not more than 90 degrees and that individual treads turn through an angle of 30 degrees, i.e., only three winders are allowed.

4. **Provisions of the Building Code**

9.8.5.3. Winders

(1) Stairs within dwelling units may contain winders that converge to a centre point provided the winders turn through an angle of not more than 90 degrees and individual treads turn through an angle of 30 degrees.

(2) Only one set of winders described in Sentence (1) shall be permitted between floor levels.

5. **Applicant's Position**

The Applicant submitted that although the subject stairs do contain six winders, in their opinion, the differences are slight and would not mean a reduction in safety. Measured at the centre of the stairs, they noted that the width of the run on each stair, as constructed, is 228 mm. This dimension exceeds the minimum run set out in Sentence 9.8.3.1.(1).

The Applicants are also providing handrails on both sides of the subject stairs and additional stair lighting.

6. **Chief Building Official's Position**

The Respondent submitted that Sentence 9.8.5.3.(1) of the Building Code allows three winders. The stairs as built have six.

7. **Commission Ruling**

It is the decision of the Building Code Commission that the stair containing six winders provides sufficiency of compliance with Sentence 9.8.5.3.(1) of the Ontario Building Code.

8. **Reasons**

i) Handrails are provided on both sides of the stair for greater safety.

ii) Increased lighting is provided within the stairwell.

iii) Stair configuration provides a greater interior stair run than might be achieved through a winder built to Sentence 9.8.5.3.(1) of the Ontario Building Code.

iv) The interior handrail forces users to travel on a wider portion of the stair.

Homeowners
32 Waverley Road
Toronto, Ontario
The Applicant

Mr. Michael Swann
Building Plan Examiner
City of Toronto
For the Respondent

RULING

1. **The Applicant**

   Ms. Jane Lovell and Mr. Stuart Button are persons to whom a building permit was issued under the *Building Code Act, 1992* to renovate their existing two storey house at 32 Waverley Road, Toronto, Ontario.

2. **Description of Construction**

   The Applicants renovation added a second storey addition at the rear of their existing two storey house. Attached to the new addition is a second storey deck which is partially cantilevered over the rear wall of the first floor. Including the new addition, the total area of the house is 1,217 ft2. The house is described as having a Group C - residential occupancy.

   The Applicants had proposed to attach an exterior spiral staircase that would connect the rear, second floor deck to an existing grade level deck. The proposed spiral staircase is made of steel and comes as a pre-manufactured kit. The basic components of the kit includes a 3 inch diameter pole, heavy 12 gauge formed steel treads which are welded to a 4 inch steel collar that slide over the pole, a 9 inch diameter base plate to fasten the pole, and a vinyl handrail with railing spandrels. The standard kit designed for a one storey height is equipped with 11 treads.

3. **Dispute**

The issue at dispute between the Applicant and the Respondent is whether the proposed spiral stairs provide sufficiency of compliance with Article 9.8.5.2. of the Ontario Building Code. In particular, the dispute revolves around whether the proposed stairs meets the average run required of 200 mm (7 7/8 inches) (as measured in the middle of the stairs) and the minimum run required of 150 mm (5 7/8 inches).

4. **Provisions of the Building Code**

9.8.5.2. Curved Stairs not in Exits

Except as permitted in Article 9.8.5.3., a curved stair not required as an exit shall have an average run of not less than 200 mm (7 7/8 in) and a minimum run of 150 mm (5 7/8 in) and shall have rises conforming to Article 9.8.3.1.

5. **Applicant's Position**

The Applicants submitted that while the proposed stairs may not meet the provisions for run requirements of Article 9.8.5.2., they have provided additional safety measures to create sufficiency of compliance. For instance, they plan to add non-slip treads, additional lighting, a gate at the second storey entrance to the stairs, and additional balustrades (railing spandrels).

The Applicants also indicate that their house has internal stairs that act as the primary means of egress. Finally, they note that inquiries made to the neighbouring municipality of Scarborough found that its building department would have approved the subject stairs.

6. **Chief Building Official's Position**

The Respondent submitted that the proposed spiral stairs are not permitted under Section 9.8 of the Building Code. They cite Sentence 9.8.2.1.(2) which allows a set of stairs to have a curved and straight portion. They indicate, however, that these stairs are entirely curved from top to bottom.

The Respondent also notes that the run of the subject stairs does not meet Code. In doing so, they have applied Sentence 9.8.3.1.(1) which requires that exterior stairs serving a dwelling unit must have a minimum run of 210 mm (8 1/4 in). The subject stairs, they argue, do not even meet the lesser run requirements found in Article 9.8.5.2.

7. **Commission Ruling**

   It is the decision of the Building Code Commission that the proposed exterior spiral stair does not provide sufficiency of compliance with Article 9.8.5.2. of the Ontario Building Code.

8. **Reasons:**

   i) The run, rise and stair width do not comply with the Ontario Building Code.

   ii) Limited proposals were provided to reduce the hazards associated with travel down the stair.

RULING

1. **The Applicant**

   Mr. Mike Jones, Vice President, Exal Aluminium Inc., is a person who is applying for a building permit under the *Building Code Act, 1992* to upgrade the fire safety performance of the aluminium manufacturing plant, especially the two level interior office space at Exal Aluminium Inc., Aurora, Ontario.

2. **Description of Construction**

   Exal Aluminium manufactures extruded aluminium products at their 95 Dunning Avenue location in Aurora, Ontario. The plant was originally constructed in 1960 and has been added to during several phases, the latest being completed in 1995.

   The building is described as a noncombustible, one storey structure, with a total building area of 16,648 m2. There are several mezzanines located in the older areas of the plant that serve as the

lunchroom, change rooms and offices. Some of the existing mezzanine structures are constructed of combustible materials.

The building is equipped with a fire alarm system, a standpipe and hose system and a supervised, automatic sprinkler system that serves the entire plant, except for the older office mezzanine area which is separated from the remainder of the building by a masonry wall. The structure is classified as having a Group F, Division 2 major occupancy.

During the last construction phase a one storey addition (the "95 addition") was added to the south end of the existing building. As this project was nearing completion, a two level mezzanine, composed of combustible construction (wood), was added as office space along the west exterior wall of the plant where the '95 addition intersects with the older building. The upper level of this mezzanine is considered to be enclosed and has an area of roughly 112 m2. The sprinkler system in the plant provides some protection for the new mezzanine. The mezzanine was not detailed in the plans submitted and approved for the '95 addition.

The existing construction of the mezzanine is 2 x 4 wood stud walls, 2 x 12 wood joists and 5/8 inch tongue and groove plywood. The plywood floor is covered by vinyl composition tiles. Both the upper and ground floor levels have an acoustic panel suspended ceiling. (The ceiling space on both levels is used as a return air plenum.) The interior walls of the offices are covered by half inch gypsum board, whereas the exterior mezzanine walls that face into the rest of the plant are sheathed with 7/16 inch aspenite and are covered with a pre-finished metal cladding. The mezzanine floor assembly is supported on load bearing wood stud walls that run from the concrete plant floor to the underside of the floor joists.

The sprinkler system in the plant extends at roof level above the mezzanine area. This system, covering the subject area was installed in 1995, and is designed to meet the requirements for Ordinary Hazard Group 2, including the standards for sprinkler spacing. The system complies with NFPA-13 for the occupancy of the building. Below the acoustic tiles and between the ceiling panels and the wood joists of the new office area sprinklers are also installed. This is also served by the 1995 system and is equipped with an 8 inch fire protection water service. The sprinkler system in the mezzanine is consistent with the combustible concealed spaces requirements of NFPA-13-1991, 4-4.1.7.1.1. and 4-4.1.7.1.2. and it is designed to meet the requirements for a Light Hazard occupancy.

3. **Dispute**

The issue at dispute between the Applicant and the Respondent is whether the proposed fire safety upgrades for the mezzanine provide sufficiency of compliance with the requirements of OBC Article 3.2.2.54. Buildings covered by this provision must be of noncombustible construction, and fully sprinklered, while roof assemblies and mezzanines, including supports, must have a fire-resistance rating of at least 1 h. As currently built, the new mezzanine is neither noncombustible nor does it have a 1 h fire-resistance rating.

4. **Provisions of the Building Code**

Article 3.2.2.54. Industrial Buildings, Division 2, up to 6 Storeys

(1) A building classified as Group F, Division 2 shall conform to Sentence (2) provided the building

(a) is not more than 6 storeys in building height,

(b) if unsprinklered, has a building area not more than the value in Table 3.2.2.V., and

(c) if sprinklered, is not more than twice the area limits of Clause (b).

(2) The building shall be of noncombustible construction, and

(a) floor assemblies shall be fire separations with a fire-resistance rating of not less than 2 h,

(b) mezzanines shall have a fire-resistance rating of not less than 1 hr,

(c) roof assemblies shall have a fire-resistance rating of not less than 1 h, and

(d) all loadbearing walls, columns and arches shall have a fire-resistance rating not less than that required for the supported assembly.

5. **Applicant's Position**

The Applicants propose several measures to provide a level of safety that, in their view, would be comparable if the mezzanine was made of noncombustible construction and had a fire-resistance rating of 1 h, i.e., if it complied with Article 3.2.2.54.

Primarily they intend to upgrade the sprinkler system within the mezzanine by replacing the existing heads with quick response sprinklers. This would be done for both the above and below ceiling sprinkler heads. The Applicants also propose to increase the number of sprinkler heads, especially in areas of the mezzanine where coverage is inadequate. They also intend to modify the sprinkler piping to maintain a greater level of pressure and to achieve the higher design standards for an Occupancy Hazard Group 1 classification. The underside of the stairs will also be protected with a layer of 5/8 type X gypsum board. The Applicants argue that these measures would offset the presence of nonrated, combustible material found in the mezzanine, as well as providing protection for the plastic piping and wood framing installed in the plenum.

The access to exits and travel distances have also been considered by the Applicant. It is their belief that the mezzanine is not required to have an additional exit. OBC Sentence 3.3.1.5.(2) requires a mezzanine to have a second exit if the occupant load exceeds 60 persons, or the mezzanine area exceeds (in the case of an F2 occupancy) 200 m2 (2,150 ft2), or the distance of travel is greater than 25 m (82 ft). The subject mezzanine, they claim, has an occupancy of 11 persons, an area of 1,202 ft2, and its greatest travel distance is 77 ft. On these grounds, they argue that it complies fully with OBC 3.3.1.5.(2). Despite their assertion, however, the Applicant is proposing to install an additional steel, open egress stair on the mezzanine's east side, in proximity to the north end.

To improve overall safety for the occupants of the plant, the Applicants will also prepare and implement a fire safety plan for the entire building consistent with Section 2.8 of the OFC.

6. **Chief Building Official's Position**

The Respondent submitted that the proposed upgrading measures offered by the Applicant do not provide sufficiency of compliance with Article 3.2.2.54. In particular, they argue that the Code allows sprinklers to be used as a compensating measure to reduce the level fire-resistance rating of roofs, but it does not grant the same relief from the requirements for noncombustible construction, ratings for floors and their supporting structures, and flame spread ratings allowed in concealed spaces used as return air plenums.

The municipality also believes that a second egress is required for the mezzanine because, according to their measurements, the distance of travel from the remotest point on the mezzanine exceeds the limits allowed in Sentence 3.3.1.5.(2). Further, the dead end corridor length of 9 m permitted in the Code is also exceeded in the subject mezzanine.

Finally, the Respondent also notes that the fire safety plan offered by the Applicant is a requirement under the OFC

7. **Commission Ruling**

It is the decision of the Building Code Commission that the combustible interior office construction provides sufficiency of compliance with Article 3.2.2.54 of the Building Code provided the sprinkler protection and egress provisions are provided and smoke detection is provided serving the plenum spaces to shut down the mechanical system and activate the fire alarm system.

8. **Reasons:**

i) The mezzanine is less than 1% of the building floor area.

ii) The wood framing is protected by drywall or other non combustible finishes.

iii) The sprinkler system is being upgraded to ordinary hazardous group 1 with quick response heads.

iv) Improved egress facilities to serve the mezzanine are being provided, including drywall protection to the underside of the existing stair.

v) The installation of smoke detection serving office plenum space will increase early detection and limit fire spread through fan shut down.

RULING

1. **The Applicant**

   Mr. John Langley, Project Director, City of Mississauga is a person to whom a building permit was issued under the *Building Code Act, 1992* to construct a new visual and performing arts centre, known as the Mississauga Living Arts Centre, in Mississauga, Ontario.

2. **Description of Construction**

The Mississauga Living Arts Centre is a multi-purpose facility. Its two principal functions are performing arts and visual arts. For performing arts there are two main theatre spaces, the concert and recital theatres. The concert theatre provides fixed seating for 1,171 persons on three levels and 104 box type seats. The legitimate stage and fly tower of the concert theatre is separated from the auditorium seating area by 1 h fire separation and a proscenium opening that is protected by a fire curtain. The stage and fly tower a equipped with a mechanical smoke exhaust.

The recital theatre contains 400 fixed seats on three levels, however it does not possess a legitimate stage and fly tower. Both the recital and concert theatres are separated from the remainder of the building by 1 h fire separations. As well, both theatres are accessed through sound and light locks.

The visual arts facility in the building includes ceramic, sculpture, glass, wood, welding, digital arts, painting, drawing, fibre arts and print making studios. There are also classrooms, display and exhibition spaces and a gift shop. The ancillary spaces in the building include a restaurant, a kids centre and two levels of underground parking.

The building is described as 3 storeys in height, approximately 7,800 m2 in area, and made of noncombustible construction. The structure is equipped with a sprinkler system and a standpipe and hose system. It also contains a two stage fire alarm system that has a control unit/annunciator panel at the fire department/staff entrance which is located adjacent to the buildings security office. The fire alarm system is also continuously monitored and supervised.

The building is classified as having Group A, Divisions 1 and 2 major occupancies.

3. **Dispute**

The issue at dispute between the Applicant and Respondent is whether the alert signals of the fire alarm system in the Mississauga Living Arts Centre should sound in the subject building's two performing arts spaces, the recital and concert theatres. Sentence 3.2.4.19.(1) of the OBC requires that audible signal appliances must be intelligibly heard throughout the floor area on which they are installed. The sequencing for audible signalling operation is not addressed in this provision. The Applicants are proposing that the first stage alert signals, intended to notify

supervisory staff, not sound in the concert and recital theatres, unless the alarm initiating device is located within either theatre.

4. **Provisions of the Building Code**

Sentence 3.2.4.19.(1) Audibility of Alarm Signals

(1) Audible signal appliances forming part of a required fire alarm system shall be installed in a building so that alert signals, alarm signals and voice messages can be heard intelligibly throughout the floor area in which they are installed.

5. **Applicant's Position**

The Applicant submitted that the proposed alarm sequencing operation provides for consistency with OBC Sentence 3.2.4.19.(1). In their view this provision is not intended to prohibit the proposed sequencing of the two stage fire alarm signalling.

The basic sequencing of the alarm signalling operation, as proposed by the Applicant, is if a fire detection device or manual pull station is activated in any area other than the concert or recital theatres, the first stage alert signal would not sound in either theatre. If a fire detection device or manual pull station in either the concert or recital theatre is activated, the first stage alert signal would sound in the theatre of origin but not the other. In either of these two scenarios the stage/house manager may be called upon to make announcements informing the audience of the alert signal elsewhere in the building or in the other theatre since the alert signal would not be sounding.

The second stage evacuation signal would sound throughout the entire building, including the two theatres, if the evacuation timer in the fire alarm control unit expired, or if an evacuation switch was activated.

The Applicant believes that the above described alarm operation is a logical sequencing in order to prevent unnecessary confusion or panic within either theatre, while at the same time alerting supervisory staff to investigate the origin of the initial alarm and to advise them to prepare for possible evacuation. This method, they argue, also allows for orderly, direct and in-person handling of the emergency instructions only if they are considered necessary. It would also avoid performance disruption.

The Applicant also points to the National Building Code, which they feel supports their position. Provision A-3.2.4.19.(1) of the NBC states that the first stage alert signal of a two stage alarm system may be restricted to a location in the building which is continuously staffed. Their proposed alarm operation sequencing would not be as restrictive as allowed in the NBC, since the alert signal would sound everywhere in the building except the two theatres.

Finally, the Applicant also argues that this sequencing of alarm systems has been installed in other theatres in Ontario recently.

6. **Chief Building Official's Position**

The Respondent submitted that the proposed alarm sequencing does not conform to Sentence 3.2.4.19.(1). In their view the requirements of this provision clearly state that even the first stage alert signals should sound throughout the entire building, including both the concert and recital theatres.

7. **Commission Ruling**

It is the decision of the Building Code Commission that the current design of the 2 stage fire alarm system to sound the alert in all areas, except the concert and recital theatres, unless a fire is detected in these areas, provides sufficiency of compliance with Sentence 3.2.4.19.(1) of the Building Code provided that the automatic initiation of the 2nd stage evacuation signal occurs after 3 minutes, if the first stage signal is not acknowledged.

8. **Reasons**

i) The building operators have indicated that the building will be staffed by security personnel on a 24 hour/7 day basis.

ii) That there will be additional staff during performance periods.

iii) Duties and responsibilities of supervisory staff, including evacuation procedures, will be part of the fire safety plan.

iv) The building is sprinklered throughout and smoke and/or fire separations are provided at studio locations.

RULING

1. **The Applicant**

   Mr. Steven DaCosta, Owner, Extreme Fitness, is a person to whom a building permit was issued under the *Building Code Act, 1992* to renovate an existing 2 storey building to create an new health club facility (Extreme Fitness) located on the ground floor of the southerly portion of the structure at 8281 Yonge Street, Markham, Ontario.

2. **Description of Construction**

   The Applicant has renovated an existing 2 storey, 4,059 m2 (43,670 ft2) building to include an new health club, known as Extreme Fitness, in the southern end of the structure. The Extreme Fitness club occupies some 2,415 m2 (26,000 ft2) of the building. The other tenancy in the building, located at the north end, occupies the remaining portion of the structure, including the entire second floor. While relatively small, the second storey has an area of 232 m2 (2,500 ft2), which exceeds 10% of the ground floor area of that tenancy. Separating the two tenancies in this building is a 2 h rated fire separation which extends from the foundation to the roof deck.

Located within the Extreme Fitness portion of the building is a mezzanine measuring 86 m2 (930 ft2). In order to maximize headroom clearance under the mezzanine, the Applicant utilized a flat, pre-cast concrete slab construction with steel HSS sections and steel plate for structural support. The Applicant also proposed to apply a spray-on, mastic-type coating to achieve a greater fire-resistance rating. The purpose of the mezzanine is to provide additional space for exercise equipment.

The building is composed of noncombustible construction. It contains a fire alarm and sprinkler system, both of which are monitored by an independant central station facility. The occupant load in the health club facility is 480 persons. It is served by 7 exits, which have a total aggregate capacity of 1,440 persons.

The Structure is classified as having a Group A, Division 2 major occupancy and faces one street.

3. **Dispute**

The issue at dispute between the Applicant and the Respondent is whether the pre-cast concrete mezzanine as designed, using steel HSS sections and steel plate with spray-on fire-proofing, provides sufficiency of compliance with Clause 3.2.2.22.(2)(b), which requires a 1 h fire-resistance rating.

4. **Provisions of the Building Code**

Clause 3.2.2.22.(2)(b) Assembly Buildings, Division 2, up to 5 Storeys, Any Area

(2) Except as provided in Sentence (3), the building shall be of noncombustible construction, and

(b) mezzanines shall have a fire-resistance rating of not less than 1 h,

5. **Applicant's Position**

The Applicant submitted that the Mezzanine, as designed, provides sufficiency of compliance with the 1 h fire-resistance rating requirement of Clause 3.2.2.22.(2)(b). There are numerous reasons the Applicant uses to support this view.

The nature of the occupancy, as a health club where space is required to carry out exercise activities, means that crowding would not be an issue as in other uses such as nightclubs etc.

covered by Article 3.2.2.22. There is also a low fire load in such a facility. In fact, large portions of the health club, such as the general exercise and aerobics areas, have virtually no fire load. The office areas, testing and consultation rooms would have a fire load comparable to that of a general use office area.

The Applicant also notes that the L-shaped mezzanine is located between two two large adjoining open areas, the general exercise area and the aerobics area. A fire that starts under the mezzanine area would easily be seen by anyone in those spaces, they argue. Further, the entire health club is well served by the seven egress points located on the east, west and south facing walls.

In the event of a fire in the tenancy at the north end of the building, the 2 h rated masonry fire separation would provide significant protection. As well, the Applicant indicates that the activation of the building's sprinkler and fire alarm systems would give occupants adequate notification prior to any collapse of the 2 h fire separation. Within the Extreme Fitness facility itself, the activation of the sprinkler system would most likely extinguish any fire before the structural stability of the mezzanine would be challenged.

Pertaining specifically to the mezzanine floor assembly, the Applicant argues that the application of the flame control mastic coating will provide additional fire-resistance protection to the steel components.

Lastly, it is the Applicant's view that although the Code considers the subject building to be 2 floors, even though the second storey is entirely in the building's other tenancy, which is separated by a 2 h rated fire-separation. The Code, however, does not recognize the mitigating effects of this separation on the spread of fire. Consequently, the 1 h fire-resistance rating for the mezzanine is required through the application of Article 3.2.2.22. Given the circumstances of this building, especially when considering the existence of the 2 h separation, the Applicant feels the higher mezzanine standard could be construed as onerous.

6. **Chief Building Official's Position**

The Respondent submitted that the construction of the mezzanine floor assembly does not meet the requirements of Clause 3.2.2.22.(2)(b). In particular, they point to Article 3.1.7.1. of the OBC which sets out the determination of fire-resistance ratings. It is their concern that while the mastic coating has been tested according to CAN4-S101-M and has been found to contribute to the fire-resistance ratings of certain assemblies, the particular assembly in question has not been

tested and therefore it is impossible to determine the overall rating of the assembly. As well, for the assembly in question it is not possible to apply the mastic coating on all surfaces. This reduces the overall fire-resistancy of the applied coating material.

7. **Commission Ruling**

   It is the decision of the Building Code Commission that the mezzanine provides sufficiency of compliance with Clause 3.2.2.22.(2)(b) of the Building Code.

8. **Reasons:**

   i) The building is sprinklered which is electronically supervised and remotely monitored.

   ii) The mezzanine is relatively small in comparison with the size of the building.

   iii) A partial flame control mastic coating is being applied to the steel structure supporting the mezzanine to provide additional protection.

   iv) The exit capacity for the premises is 3 times what is required based on occupant load.

   v) The 2 hr separation is provided between the health club and adjacent occupancy.

   vi) It is the opinion of the Building Code Commission that the design does not present an increase hazard to life safety from fire.

RULING

1. **The Applicant**

   Ms Jill Moir, Grey Condominium Corporation is the holder of a building permit under the *Building Code Act, 1992* to install fire separations at existing 3 storey townhouse condominiums in the Township of Collingwood, Ontario.

2. **Description of Construction**

   There are 6-12 dwelling units in each building. Each building contains upper and lower units in which one dwelling unit is located above another. The design and construction of each building was regulated by Part 9 of the Ontario Building Code as each building is not more than three storeys in height or 600 square metres in building area. Since the building is a condominium, the separation between residential suites is governed by Sentence 9.10.9.14.(3) which requires a fire separation having a fire-resistance rating of not less than 1 hour.

   The buildings are permitted by the Building Code to be of combustible construction. The buildings were constructed of a combination of combustible and non-combustible construction. The roofs are framed using timber trusses spaced 16 inches apart except at dormer locations where the roof has been constructed using conventional lumber framing. The roof trusses span parallel to these vertical fire separations except at the ensuite bath where the fire separation jogs 90 degrees and runs perpendicular to the span of the trusses. This condition exists in 18 upper units.

The vertical fire separations were originally constructed to the underside of the trusses with no fire separations within the attic space. They were recently extended through the attic space to the underside of the wood roof sheathing. This new fire separation is constructed of rated gypsum board on both sides of metal studs and is required by Article 9.10.9.10. to have a 1 hour fire resistance rating. Where the fire separation jogs around the ensuite bath, the timber trusses penetrate this new fire separation

3. **Dispute**

The dispute between the Applicant and Respondent concerns whether the installed wood roof truss penetration of the combustible 1 hour fire separation in the attic space is permitted under the Building Code.

4. **Provisions of the Building Code**

Sentence 9.10.9.14. Separation of Residential Suites

(3) Dwelling units that contain 2 or more storeys including basements shall be separated from the remainder of the building by a fire separation having a fire-resistance rating of not less than 1 hr.

Article 9.10.3.1. Fire-Resistance and Fire-Protection Ratings

Where a fire-resistance rating or a fire-protection rating is required in this Section for an element of a building, such rating shall be determined in conformance with the test methods described in Part 3, or in accordance Chapter 2 of the Supplement to the NBC 1990, or with Tables 9.10.3.A. and 9.10.3.B.

Sentence 9.10.9.10.(1) Concealed Spaces above Fire Separations

(1) Except as provided in Sentence (2), a horizontal service space or other concealed space located above a required vertical fire separation shall be divided at the fire separation by an equivalent fire separation within the space.

Article 9.10.5.1 Permitted Openings in Wall and Ceiling Membranes

(1) Except as permitted in Sentences (2) and (4), a membrane forming part of an assembly required to have a fire-resistance rating shall not be pierced by openings into the assembly unless the assembly has been tested and rated for such openings.

(2) A wall or ceiling membrane forming part of an assembly required to have a fire-resistance rating may be pierced by openings for electrical and similar service outlet boxes provided such outlet boxes are tightly fitted.

5. **Applicant's Position**

The one hour fire separation within the attic space is constructed of rated gypsum board on both sides of wood studs in accordance with Chapter 2, "Fire Performance Ratings" of the Supplement to the National Building Code of Canada, 1990. The engineered wood roof trusses span parallel to the attic fire separation except where the fire separation jogs around the ensuite bathroom. The trusses clear span the length of each dwelling unit and the trusses are spaced at 600 mm on centre. Where members of the truss penetrate the 1 hour fire separation, the gypsum board on both sides of the vertical fire separation has been tightly fitted or firestopped around each member as required by the Building Code.

The Applicant submitted that the issue raised by the Respondent regarding the collapse of the unrated roof trusses may cause premature collapse of the 1 hour fire separation in the attic only applies to firewalls and noncombustible fire separations supporting combustible construction. The requirements for firewalls and combustible construction supported by noncombustible fire separations do not apply to combustible construction supported by combustible fire separations. The Applicant is of the opinion that the Building Code does not prohibit the collapse under fire conditions of a rated vertical fire separation as a result of the collapse of unrated or lesser rated construction supported by it where the rated fire separation and unrated construction are of the same construction type. Furthermore, the Applicant submitted that the roof assembly is not required by the Code to have a fire-resistance rating.

6. **Chief Building Official's Position**

The Chief Building Official submitted that the attic fire separations of the units are required to be constructed as one hour fire separations in accordance with Sentence 9.10.9.10(1). Eighteen of the 27 upper units within the development contain 6 or 7 of the 17 trusses within the attic which penetrate the fire separation. The ceiling of these units has not been constructed as a fire rated separation.

The Respondent also submitted that the fire resistance rating of a fire separation penetrated by wood roof trusses cannot be determined by using Chapter 2, "Fire Performance Ratings" of the Supplement to the NBC 1990 because this document does not assign a time of contribution to

wallboard membranes penetrated by wood roof trusses or any other type of framing members. Approved fire tests are not known to have been conducted on such an assembly. Therefore, the fire resistance rating of the fire separations penetrated by the wood roof trusses is unknown. It is the position of the Respondent that the attic fire separations penetrated by the wood roof trusses have not been constructed in accordance with fire-resistance and fire-protection ratings under Article 9.10.3.1 and therefore do not provide a 1 hour fire resistance rating as required by Sentence 9.10.9.10.(1).

The Respondent indicated that should a fire occur in the attic of one of the units adjacent to the fire separations in question, the roof trusses which penetrate the separation could lose their integrity in as little as 5 minutes and would take the fire separation down along with them.

7. **Commission Ruling**

It is the decision of the Building Code Commission that the protection of penetrations of the 1 hr fire separation by wood trusses provides sufficiency of compliance with 9.10.9.14.(3) of the Building Code.

8. **Reasons:**

i) The penetrations by wood trusses of the fire separations are sealed and the exposed chords are protected for at least 1 foot by fire resistance rated materials.

RULING

1. **The Applicant**

   Mr. Norman Pye, Northern Pride is the holder of a permit under the *Building Code Act, 1992* to construct a poultry processing plant at 20 Scott Avenue, Paris, Ontario.

2. **Description of Construction**

   The building of Northern Pride Products Inc. is a new one storey processing plant (Group F, Division 2 major occupancy) of non-combustible construction with a building area of 8,960 square feet (832 square metres). The building does not have a fire alarm system, a sprinkler system or a standpipe and hose system. Rigid foamed plastic insulation is used in the construction of the walls and ceilings of the Production Area, Cold Room, Shipping Room and Cooler. "Kemlite Glasboards", a type of fibreglass reinforced plastic panels, are installed over the rigid foamed plastic insulation.

   The construction of the building is regulated by Article 3.2.2.51 of the Building Code. and may be of combustible or noncombustible construction used either singly or in combination, and the roof is not required to have a fire-resistance rating. The building is constructed of masonry loadbearing walls, open web steel joists and steel deck.

3. **Dispute**

The dispute between the Applicant and Respondent concerns whether the wall and ceiling installations meet the requirements of Sentence 3.1.4.2.(1) of the Building Code.

4. **Provisions of the Building Code**

Sentence 3.1.4.2.(1) Protection of Foamed Plastics

(1) Foamed plastics which form part of a wall or ceiling assembly in combustible construction shall be protected from adjacent spaces in the building, other than adjacent concealed spaces within attic or roof spaces, crawl spaces, and wall assemblies, by

(a) one of the interior finishes described in Subsections 9.29.4. to 9.29.9.,

(b) sheet metal mechanically fastened to the supporting assembly independent of the insulation, not less than 0.38 mm (0.015 in) thick and with a melting point not below 650oC (1202oF) provided the building does not contain a Group B or Group C major occupancy, or

(c) any thermal barrier that meets the requirements of Sentence 3.1.5.11.(2). (See Appendix A.)

5. **Applicant's Position**

The Applicant maintained that the plant was approved by Agriculture Canada. Due to the nature of production in the plant which requires surfaces to be non-porous to prevent bacteria, the Applicant indicated that the `glasboard' is a suitable material because it can be easily cleaned. As the plant environment is very wet and damp and there is no hydro in the walls, there is a little chance of a fire hazard. Furthermore, there is a low occupant load of 22.

6. **Chief Building Official's Position**

The wall and ceiling construction include the installation of foam plastic insulation which is not protected from adjacent spaces by a thermal barrier tested in conformance with CAN4-S124-M "Standard Method of Test for the Evaluation of Protective Coverings for Foamed Plastic" as required under the Building Code. The Applicant has installed "Kemlite Glasbord" fibre-glass reinforced plastic panels over the foam plastic insulation. "Kemlite Glasbord" has not been tested to the required standard specified in Sentence 3.1.4.2.(1). An Order to Comply was issued by the Respondent to the Applicant to provide protection between the foamed plastic insulation and the "Kemlite Glasbord" panels in accordance with the requirements of Sentence 3.1.4.2.(1) of the OBC.

7. **Commission Ruling**

   It is the decision of the Building Code Commission that the installation of `Glasbord' CPI over 1-1/2" S.M. board provides sufficiency of the compliance with Article 3.1.4.2. of the Building Code.

8. **Reasons:**

   i) The building is small (i.e) single storey and 8960 sq.ft. and is subdivided into areas no greater than 4500 sq. ft in area by masonry walls and metal doors.

   ii) The distance of travel to exits is less than required by the Building Code.

   iii) The processing area is damp and high pressure hose stations are available which are intended for wash down but could be used for fire fighting purposes.

   iv) Ambient temperature alarms are located in the processing area and storage to which would alert the occupants of a fire when temperatures exceed 45o and 34o F respectively.

   v) The occupant load is low (i.e. 22 persons).

RULING

1. **The Applicant**

   Mr. Rupert Bronsdon, President, Lighthouse Point Yacht and Tennis Club Inc., is a person who has applied for a permit under the *Building Code Act, 1992* to construct a new residential structure, known as Phase Three, at the Lighthouse Point Yacht and Tennis Club Inc., Highway # 26 West, Town of Collingwood, Ontario.

2. **Description of Construction**

   The proposed Phase Three project at the Lighthouse Point Yacht and Tennis Club is a three storey structure which will be separated into two buildings by a 2 h firewall. One building will be 753 m2 (8 110 ft2) and the other will be 659 m2 (7 094 ft2), for a total area of 1 412 m2 (15 204 ft2). The Phase Three structure will be made of combustible construction and is classified as having a Group C (residential) major occupancy. The structure does not have a standpipe and hose system nor a sprinkler system. It is equipped with a fire alarm system.

   The Applicant proposes to terminate the 2 h firewall between the two buildings of Phase Three on the underside of the concrete roof slab. The roof slab, however, is present on one side of the firewall only. They do not propose to construct a parapet extending above the roof.

   The Applicant is also proposing to construct wood and drywall truss assemblies for the attic, in which the drywall is applied to the sides of the wood trusses.

3. **Dispute**

The issue under dispute between the Applicant and the Respondent is whether the proposed termination of the firewall on the underside of the concrete roof slab can occur on one side only of the subject firewall. (The municipality is regarding the Phase Three project as Part 9 building, however, Article 9.10.11.3 refers to Subsection 3.1.10. for the requirements for firewalls.) Sentence 3.1.10.3.(2) allows firewalls to terminate on the underside of reinforced concrete roof slabs provided that the same roof slab has a fire-resistance rating of 1 h on both sides of the firewall. The Applicant believes that the firewall and roof slab assembly as designed provides sufficiency of compliance with this provision. As well, both the Applicant and Respondent request clarification whether the wood trusses themselves contribute 5 minutes to the fire-resistance rating of the wood and drywall truss assembly provided in the attic of the Phase Three building.

4. **Provisions of the Building Code**

3.1.10.3. Continuity of Firewalls

(2) A *firewall* is permitted to terminate on the underside of a reinforced concrete roof slab provided
(a) the roof slab on both sides of the *firewall* has a

(i) *fire-resistance rating* of not less than 1 h if the *firewall* is required to have a *fire-resistance rating* of not less than 2 h, or

(ii) *fire-resistance rating* of not less than 2 h if the *firewall* is required to have a *fire-resistance rating* of not less than 4 h, and

(b) there are no concealed spaces within the roof slab in that portion immediately above the *firewall*.

5. **Applicant's Position**

The Applicant submitted that both the proposed firewall and roof truss assemblies provide sufficiency of compliance. Regarding the firewall and roof slab assembly, the Applicant argued that the combination of the 2 h firewall (8 inch semi-solid concrete block) and the 10 inch thick precast concrete roof slab would provide adequate containment and prevent the spread of fire between one building of Phase Three and the other. It is their contention that the proposed design

obviates the need for both the concrete roof slab on the other side of the firewall and a parapet extending above the roof line. The Applicant is concerned with drainage problems if the sloped portion of the roof terminates at a parapet.

The fire-resistance ratings of roof truss assembly are set out in OBC Article 3.1.7.1. (Determination of Ratings), which refers to Chapter 2, "Fire Performance Ratings" of the Supplement to the National Building Code 1990. Subsection 2.3 of the Supplement, in particular Table 2.3.C., indicates that a wood truss assembly has a 5 minute rating. The Applicant believes that this provision supports their assertion regarding the contribution of the wood truss itself to the overall fire-resistance rating of the assembly. When combined with 40 minute rated drywall applied on both sides of the wood truss, they argue that the overall fire-resistance rating of the subject truss assembly is 45 minutes.

6. **Chief Building Official's Position**

The Respondent submitted that the proposed firewall and roof slab design does not provide sufficiency of compliance with the Building Code. In their view, the firewall is allowed to terminate on the underside of a concrete roof slab, but as per 3.1.10.3.(2)(a) this must be done on both sides of the firewall. In addition, because Phase Three is separated by a 2 h firewall, the OBC requires that the concrete roof slab must have a fire-resistance rating of at least 1 h on both sides. Alternatively, the Respondent notes that with a concrete roof slab on one side only, and therefore no possibility to terminate the firewall on both sides, the Applicant must provide a parapet. Such a parapet should extend 150 mm above the roof line in accordance with Clause 3.1.10.4.(1)(a) and would provide the necessary continuity of the firewall.

As the municipality is also seeking clarification on the fire-resistance rating of the roof truss, they did not offer any arguments regarding this issue.

7. **Commission Ruling**

It is the decision of the Building Code Commission that the firewall provides sufficiency of compliance with 3.1.10.3.(2)(a) of the building Code provided that:

a) the cores or the cellular concrete slabs terminating at the firewall are filled with noncombustible materials, and

b) the combustible insulation on the roof of the concrete slab is replaced with noncombustible insulation, the width of the firewall.

It is also the decision of the Building Code Commission that the roof truss detailed protected with 5/8 inch fire-rated drywall does not provide adequate support for the drywall and consequently does not provide sufficiency of compliance with the Building Code, for a 3/4 h fire-rated wall assembly.

8. **Reasons:**

Insufficient evidence was provided for the truss configuration to ensure the fire-rated drywall is mounted in accordance with fire performance ratings found in the NBC Supplement for wall assemblies.

RULING

1. **The Applicant**

   Mr. Paolo Presutti, Director of Construction, Fortinos Supermarkets Ltd., is a person who has applied for a permit under the *Building Code Act, 1992* to renovate an existing retail supermarket by constructing a sit down eating area in the building at Fortinos Woodbridge, 3900 Highway # 7, City of Vaughan, Ontario.

2. **Description of Construction**

   The existing Fortinos Woodbridge facility at the City of Vaughan is a one storey building approximately 67 865 ft2 which is made of noncombustible construction. The building is classified as having a Group E (Mercantile) major occupancy. Currently, the structure does not have a standpipe and hose system. It is equipped with a fire alarm and sprinkler system.

   The applicant proposes to expand the existing sit down cafeteria area from 30 to 82 seats. At one point 57 seats were provided in this area but 27 were removed at the request of the municipality. The proposed renovation of this area would not only reinstate the 27 removed seats, but would add 25 new seats.

3. **Dispute**

   The issue under dispute between the Applicant and the Respondent is the number of water closets that must be provided within the renovated supermarket, including the expanded cafeteria area. Determinations of occupant load has a direct bearing on the minimum number of washrooms that must be provided. The Applicant has designed the subject supermarket based on the actual occupant load, which they estimate to be approximately 425 persons, including 82 in

the cafeteria area. The municipality has based its calculations of the occupant load of this building on Article 3.1.16.1., which states that when calculating the number of persons for a mercantile occupancy, the figure to use is 3.7 m2 (39.8 ft2) per person. This has resulted in occupant load determination of 1 162 persons, 85 of which are allocated to the restaurant. The discrepancy between these calculations has resulted in a dispute regarding the number of water closets that should be provided in the building.

4. **Provisions of the Building Code**

3.1.16.1. Occupant Load Determination

(1) The occupant load of a floor area or part of a floor area, or of a building or part of a building not having a floor area, shall be based on
(a) the number of seats in assembly occupancies having fixed seats,

(b) 2 persons per sleeping room or sleeping area in a dwelling unit or suite, and

(c) the number of persons

(i) for which the area is designed, or

(ii) determined from Table 3.1.16.A. for occupancies other than those described in Clauses (a) and (b).

(2) Where a floor area or part thereof has been designed for an occupant load other than that determined from Table 3.1.16.A., a permanent sign indicating that occupant load shall be posted in a conspicuous location.

(3) For the purposes of this Article, mezzanines, tiers and balconies shall be regarded as part of the floor area.

(4) Where a room or group of rooms is intended for 2 or more occupancies at different times, the value to be used from Table 3.1.16.A. shall be the value which gives the greatest number of persons for the occupancies concerned.

(5) In dining, alcoholic beverage and cafeteria space, the maximum occupant load shall be designed by using an area per person of 0.6 m2 (6.5 ft2).

5. **Applicant's Position**

The Applicant submitted that the occupant load for the proposed renovation of the Fortinos Woodbridge should be based on the actual number of people that can realistically use the supermarket. The retail portion of the store is 4 296 m2, which based on a Group E (mercantile) occupancy, using Table 3.1.16.A., results in an occupant load of 1 162 persons. As the Applicant notes, however, this calculation is based on the gross retail floor area and does not subtract space for display units and fixed shelving, which is entirely unusable in terms of occupant load. Even at their busiest time of the year, the Christmas holiday season, the Applicant estimates that roughly 375 to 400 shoppers is the maximum that the facility can accommodate. In fact, only 400 shopping carts are provided. The figure of 400 shoppers includes 57 persons seated in the cafeteria area. (This number was eventually reduced to 30 at the request of the City of Vaughan.)

The Applicant now wishes to reinstate the previously removed 27 cafeteria seats and to further increase the seating capacity of that area by 25, for a total of 82 people. This would raise the total retail area occupant load to 425 persons. It is this number that the Applicant wants to use as the basis for calculating how many water closets to provide. To do this, they are proposing, according to Sentence 3.1.16.1.(2), to post a permanent sign indicating the specific occupant load of the retail floor area.

Stemming from this adjusted occupant load, the Applicant has calculated the water closet requirements as follows. For the public in a Group E occupancy with 343 persons, divided equally for men and women, Sentence 3.6.4.2.(24) indicates that 1 male and 2 female washrooms are required. (The issue of staff washrooms for the mercantile occupancy does not seem to be a matter of dispute since 6 are available on the mezzanine level.) As well, Sentence 3.6.4.2.(16) stipulates that the minimum number of water closets provided in a restaurant with an occupant load of 82 (41 females and 41 males) shall be 2 for each sex. The Applicant is proposing to provide a total of 7 water closets, 4 female and 3 male. On this basis, they believe that the ground floor is adequately served with water closets.

Finally, the Applicant is of the opinion that Clause 3.6.4.2.(24)(a) allows them to consider the staff washrooms as part of those required, even though they are on a different floor, as long as they are made accessible to the public.

6. **Chief Building Official's Position**

The Respondent submitted that the Fortinos Woodbridge, being considered a mercantile building under the OBC, has an occupant load of 1 162 persons. This includes 85 people in the cafeteria. It is their view that the water closets should be provided based on the higher occupant load. Their particular concern is the proposal to enlarge the cafeteria. In their opinion, the cafeteria should be installed with 6 washrooms, 3 for each sex. Sentence 3.6.4.2.(18) states that a cafeteria having more than 40 seats must have separate water closets for staff. This would increase the 2 washrooms per sex required under Sentence 3.6.4.2.(16) to 3 for each.

The 6 washrooms required in the cafeteria, they note, would be in addition to the washrooms required in the rest of the retail space. Furthermore, the municipality does not believe the staff washrooms can be counted as being part of those required because during a site inspection it was discovered that these washrooms were inaccessible due to locked doors separating the staff area on the mezzanine level.

7. **Commission Ruling**

It is the decision of the Building Code Commission that the washroom facilities provide sufficiency of compliance with the requirements of the Building Code provided the washroom facilities on the mezzanine level are made accessible to the public and that permanent marking is provided on the lower level washrooms indicating additional washroom facilities are available on the mezzanine level and instructions on how they may be accessed.

8. **Reasons:**

i) Increasing the seating capacity of the eating area of the supermarket to 85 increases the need for washroom facilities in the supermarket.

ii) Washroom facilities on the mezzanine level that are intended primarily for staff use, can be made available to the public.

iii) The signage may be used to direct accessibility to the mezzanine level washrooms.

RULING

1. **The Applicant**

   Mr. Karl Stennson, Vice President, Sheridan Nurseries Ltd., is a person who has applied for a permit under the *Building Code Act, 1992* to renovate an existing, enclosed wood frame building to provide for an expansion of their current retail area and to construct a new open-air, covered sales facility at Sheridan Nurseries Ltd., 4077 Highway # 7, Town of Markham, Ontario.

2. **Description of Construction**

   The existing building at Sheridan Nurseries in Markham is a 30 year old, enclosed, one storey structure that has been used for nursery-related sales and as a greenhouse. The building is 600 m2, which includes a 160 m2 greenhouse. It is composed of combustible construction and is classified as having a Group E (mercantile) major occupancy. Currently, the structure does not have a standpipe and hose, fire alarm, nor a sprinkler system.

   The proposed work at Sheridan Nurseries has two separate components. One of these is the renovation to the above described existing building, while the other is the construction of a new

open-air sales facility. To distinguish between these two aspects of the project, the former shall be known as the enclosed retail building, while the latter shall be called the covered sales facility.

Regarding the enclosed retail building, the Applicant proposes to demolish the existing greenhouse and replace it with a one storey, enclosed addition. The total area of this renovated building would be 1 435 m2 (15 447 ft2). This would include a small office area (382 ft2), a storage area (2 268 ft2), while the rest of the space would be devoted to retail sales. The conventional, solid roof covering the existing building will remain in place. The addition to the enclosed retail building, however, will be covered by a polyethylene roof system manufactured by Westbrook Greenhouse Systems Ltd. The roof assembly is a modular greenhouse system composed of two 6 mm layers of polyethylene sheets, with pressurized air between them to increase rigidity, supported on a steel frame. The walls of the addition will be constructed of aluminum thermowall panels and tempered glass in aluminum frames.

The design of the enclosed retail building will allow for fire route access from 3 streets. As such, it is not necessary that the building be equipped with a standpipe and hose system and a sprinkler system. This is also allows it to be made of unrated combustible construction. The occupant load, based on OBC Table 3.1.16.A., is deemed to be 388 persons. By exceeding 300 persons, according to OBC 3.2.4., a fire alarm and detection system will be installed. The building will also be equipped with portable fire extinguishers. Furthermore, egress from the enclosed sales building will be based on 6.1 mm width per person and the exits will be located so that the maximum distance of travel will be 30 m or less.

The covered sales facility, located roughly 3 m from the enclosed sales building, is an entirely new structure. It is intended that this facility be open air, i.e., constructed without walls. The proposed use of this 1 615 m2 (17 388 ft2) structure is as a seasonal sales area. The roof for the covered sales facility is exactly the same as that described for the addition to enclosed sales building.

This structure, if it were assumed to be a typical mercantile occupancy, the potential occupant load would be 437 persons. Having no walls, egress from the covered sales facility is not a concern. The maximum travel distance from any where inside this structure to beyond the perimeter of the roof will not be more than 30 m.

3. **Dispute**

There are several issues under dispute between the Applicant and the Respondent. The first issue is whether the polyethylene roof assembly for the proposed addition to the enclosed sales building should conform to the requirements of Article 3.2.4.18. of the OBC. This provision states that all buildings shall have a class A, B or C roof, with the exception of tents and air supported structures. The Respondent holds that the polyethylene roof should conform to 3.2.4.18. The municipality is also concerned that the polyethylene roof assembly has not been tested for conformance with the appropriate safety standards (CAN/ULC S-107-M87) as referenced in Sentence 3.2.3.18.(1). The Applicant, on the other hand, believes that this Article is not applicable to polyethylene "skylights".

The second issue is whether the open-sided covered sales facility, with its polyethylene roof membrane, should be governed by the requirements of Subsection 3.1.6., which deal with tents, air-supported and temporary structures. The Respondent believes that the covered sales facility is a tent and that the provisions of 3.1.6. are relevant. They also believe that, according to Article 3.1.6.5., the facility should comply with the requirements of CAN/ULC S-109-M, which sets out standards for flame-resistance of materials found in tents, etc. The Applicant holds that the covered sales facility is not a tent, meaning that 3.1.6. are not relevant.

A third issue, common to both proposed structures, is whether the roof systems demonstrate sufficiency of compliance with the various relevant provisions of the OBC.

4. **Provisions of the Building Code**

3.2.3.18. Roof Coverings

(1) Except as provided in Sentence (2), every building shall have a Class A, B or C roof covering as described in Subsection 3.1.15.

(2) Roof coverings are not required to have a Class A, B or C rating for

(a) tents and air-supported structures, and

(b) buildings of Group A, Division 2 occupancy not more than 2 storeys in building height and not more than 1 000 m2 (10,800 ft2) in building area provided the roof covering is underlaid with noncombustible material.

3.1.6. Tents, Air-Supported Structures and Temporary Structures

3.1.6.1. Means of Egress

Tents, air-supported structures and temporary structures shall conform to Section 3.3 and 3.4.

3.1.6.2. Application

(2) Air-supported structures shall not be used for Groups B, C or Group F, Division 1 major occupancies or for classrooms.

(3) Air-supported structures shall be designed primarily as open floor space without interior walls, mezzanines, intermediate floors or similar construction.

(5) For the purposes of this Subsection, a temporary structure means a building or structure intended to be erected and used for a period of not more than 12 months.

3.1.6.3. Clearance to Other Structures

(1) Except for tents used for camping and other personal uses and except as provided in Sentences (2), (3) and (4), every tent, air-supported structure and temporary structure shall conform to Subsection 3.2.3.

(2) Tents and air-supported structures shall not be erected closer than 3 m (9 ft 10 in) to other structures on the same property except as provided in Sentences (3) and (4), and shall be sufficiently distant from one another to provide an area to be used as a means of emergency egress.

3.1.6.4. Clearance to Flammable Material

The ground enclosed by a tent or air-supported structure and for not less than 3 m (9 ft 10 in) outside of such structure shall be cleared of all flammable material or vegetation that will carry fire.

3.1.6.5. Flame Resistance

Every tent and all tarpaulins and decorative materials used in connection with tents and air-supported structures shall conform to CAN/ULC S-109-M, "Standard for Flame Tests of Flame-Resistant Fabrics and Films".

3.1.6.8. Design of Temporary Structures

(1) Except for tool sheds or similar structures, the structural components of a temporary structure shall be designed in conformance with

(a) Subsection 4.1.6. for the intended use,

(b) Subsection 4.1.7. for snow and rain, and

(c) Subsection 4.1.8. for wind.

5. Applicant's Position

The Applicant submitted that the proposed roof membrane for both the enclosed sales building and the covered sales facility is not a "roof covering". They argue that the classes of roof structures described in Article 3.2.3.18. are intended for typical, permanent roof coverings that have a water-resistant material applied as an additional layer. The CAN/ULC S-107-M standard is designed to test the fire resistance of these water proofing layers, especially the potential for a fire to develop on top of a solid roof covering. Such a situation, the Applicant notes, cannot occur on a polyethylene film. The fire would simply burn through the polyethylene. The Applicant therefore concludes that the referenced roof standard does not apply. In their view, the proposed roof structures are essentially large skylights, and in their experience CAN/ULC S-107-M also does not apply to skylights.

The Applicant holds that permitting the enclosed sales facility under the OBC is a straightforward matter. The Building Code, they argue, allows certain single storey buildings to be built with unrated, combustible construction. The interior flame-spread rating of such a building must not exceed 150. As the Applicant notes, the proposed polyethylene assembly meets both these conditions. Further, because there are no corridors requiring fire-separation from other parts of the floor area, they feel that there would be no limits placed on a combustible skylight (OBC 3.1.13.5.). Indeed, the Applicant notes that the Building Code would allow them to virtually cover the entire roof of a combustible building with acrylic skylights. However, as they point out, acrylic skylights have a higher flame-spread rating, and because they are double glazed they have a greater fire load and consequently a higher fire hazard.

In their opinion then, sufficiency of compliance is not an issue regarding this building. As demonstrated above, they believe the building does comply with the relevant OBC provisions.

The Applicant also submitted that polyethylene, as a material, has been tested under ULC S-102.2 and was found to have a flame-spread rating of less than 25. They also noted that this type of polyethylene-covered greenhouse system has been used previously in Ontario.

The same argument regarding limitlessness of skylights can be applied to the covered sales facility. This structure is classified as a Group E occupancy. The maximum size of a combustible building with such an occupancy is 1 500 m2 (16 100 ft2). The proposed covered sales facility exceeds this limit by 115 m2. This larger capacity is tolerable, the Applicant argues, due to the fact that the covered sales area has no walls, any fire that started would spread slowly because of the small fire load represented by the polyethylene. Such a fire would likely not cause many problems concerning gases or smoke. The polyethylene covering above the fire would burn away quickly and the fire would vent up and out of the facility, or it would vent along the arches of the ceiling and out the open sides. In addition, egress is possible in many locations and the travel distance is less than 30 m. It is for these reasons that the Applicant believes that the covered sales facility does meet the intended level of life safety in the OBC and as such provides sufficiency of compliance.

The open-sided, covered sales facility is not a tent the Applicants also argue. The proposed structure has little in common with a tent. Although to be used seasonally, the covered sales facility has far more permanence. As well, unlike a typical tent, there are no walls. The facility is not air-supported either, the Applicants claim. The pressurized air in between the polyethylene films is not a vital support mechanism for the roof assembly. Based on these arguments, the Applicant is of the opinion that the covered sales facility should not be subject to the requirements of Subsection 3.1.6.

6. Chief Building Official's Position

The Respondent submitted that the proposed enclosed sales building is required to have a class A, B or C roof covering according to Sentence 3.2.3.18.(1) and the CAN/ULC S-107-M87 standards. In their view, the subject polyethylene roofing material had been adequately tested for conformance with the above referenced standard.

Regarding the covered sales facility, the municipality recognized that it was a difficult building to classify, nevertheless they felt that it would be appropriate to consider this structure as a tent and to apply the provisions of 3.1.6. Such a classification would allow the covered sales facility to be located within 3 m of the enclosed sales building. This would also allow the Applicant the opportunity to be released from the requirement to provide sprinklers, they added. Here too, however, they were concerned about the performance of the polyethylene with respect to flame-resistance.

7. Commission Ruling

It is the decision of the Building Code Commission that the polyethylene film covering the

Sheridan Nurseries retail building provides sufficiency of compliance with Article 3.2.3.18 of the Building Code and the covered sales facility using a rain shield of polyethylene film is for the purposes of the application of the Building Code considered a tent and the fabric provides sufficiency of compliance with Article 3.1.6.5 of the Building Code and the tent is subject to the spatial separation requirements of Article 3.1.6.3 of the Building Code.

8. Reasons:

i) The building is used as a garden centre and contains limited fuel load.

ii) Opinion evidence provided by ORTECH on polyethylene flame spread indicates a value of less than 25 as an interior finish.

iii) The test for fabric flammability conducted by ORTECH using standard ASTM D-635 provides data on the limited ability of the film to propagate flame.

iv) The building is permitted to be of combustible construction under the Building Code.

v) The enclosed retail building will satisfy all other Building Code requirements including structural, fire alarm and egress.

vi) The fuel load for the polyethylene film used is approximately 20 times less than for other rigid plastics.

vii) The film will melt away and vent fires under fire conditions.

viii) It is the opinion of the Building Code Commission that the proposed use of polyethylene film in this application does not increase the hazard to life safety from fire.

Dated at Toronto this 9th day in the month of July in the year 1997 for application number 1997-27.

BCC Ruling No. 97-25-567

BUILDING CODE COMMISSION DECISION ON B.C.C. #97-25-567

AND IN THE MATTER OF Sentences 3.4.6.4.(4) and 3.4.6.4.(5) of "the Building Code" (Ontario Regulation 419/89 as amended by Ont. Reg. 183/88, 581/88, 11/89 and 115/89).

RULING

The Applicant

Mr. Marty Koshman, Facilities Manager, Newbridge Networks Corporation, is a person who has received a permit under the *Building Code Act, 1992* to renovate a 3 and 6 storey office building by constructing a 3 and 10 storey addition to the building at Newbridge Networks Corporation, City of Kanata, Ontario.

1. **Description of Construction**

   The Newbridge Networks Corporation office is made of noncombustible construction. The existing building is 3 and 6 storeys and the addition is a 3 and 10 storey structure. The areas of the existing and new portions of the building are 13 082 m2 and 24 250 m2 respectively. The structure has a standpipe and hose system and a fire alarm system. It does not have a sprinkler system. The building is classified as having Group D (office) use as its major occupancy.

2. **Dispute**

The issue under dispute between the Applicant and the Respondent is whether the handrail height at the landings of the exit stairs provides sufficiency of compliance with Sentences 3.4.6.4.(4) and 3.4.6.4.(5). Sentence 3.4.6.4.(4) sets minimum (800 mm [2 ft 7 in]) and maximum (920 mm [3 ft]) heights for handrails on stairs. In addition, Sentence 3.4.6.4.(5) requires that at least one handrail in a stairway be continuous throughout, except where it may be interrupted for a doorway or a newel. The height of the continuous handrails in dispute, as measured to the floor of the landings in the new addition of the Newbridge Networks Corporation building, is 1 070 mm. In the stairways of this addition there are handrails on both the wall side and the open stair side. It is the open stair side that has the continuous handrail.

3. **Provisions of the Building Code**

3.4.6.4. Handrails

(4) Handrails on stairs and ramps shall be not less than 800 mm (2 ft 7 in) and not more than 920 mm (3 ft) high, measured vertically from a line drawn through the outside edges of the stair nosing or from the surface of the ramp, except that handrails not meeting these requirements are permitted provided they are installed in addition to the required handrail.

(5) Except as required in Sentence (9), at least one handrail shall be continuous throughout the length of a stairway including landings except where the handrail is interrupted by doorways or newels at changes in direction. (See Appendix A.)

4. **Applicant's Position**

The Applicant submitted that the handrails as designed and built meet all the requirements and the intent of the relevant provisions of the OBC. The height of the handrails on both sides, as measured on the stairs themselves, is 920 mm (3 ft), which is consistent with Sentence 3.4.6.4.(4). The handrails on the wall side extend horizontally for 300 mm (11 3/4 in) at the top and bottom of the stairs over the landings. This too, they note, is consistent with the Code, in particular, Sentence 3.4.6.4.(7).

Regarding the railing at the open stair side, it is their view that the Code does not stipulate that the continuous railing is required to have a consistent height throughout the length of the stairway. Sentence 3.4.6.4.(5) simply states that at least one handrail should be continuous. As the Code does not specifically require consistency of height for the continuous railing, they

believe that the subject railings satisfy Sentence 3.4.6.4.(5). They note that many other buildings in the area are designed the same way.

5. **Chief Building Official's Position**

The Respondent submitted that the height of the continuous handrail at the landings is inconsistent with the handrail height on the stairs. They believe this discrepancy may cause problems for blind and visually impaired persons using these stairs. In particular, they feel that a handrail height at the landing level not consistent with that of the stairs may mean that such individuals would have difficulty determining the height of the first and last risers in a flight. Indeed, this height inconsistency would not make apparent when the stairs, in relation to the landings, actually begin and end. Since the handrails in the stairways of the addition to the Newbridge Networks Corporation building are not of uniform height, the Respondent is of the view that they contravene Sentences 3.4.6.4.(4) and 3.4.6.4.(5) of the OBC.

6. **Commission Ruling**

It is the decision of the Building Code Commission that the handrail on the stairs complies with the requirements of the Building Code.

7. **Reasons:**

Construction drawings indicate that the handrail would provide sufficient warning to visually impaired individuals of changes in direction and in determining where stairs begin and end.

Dated at Ottawa this 3rd day in the month of July in the year **1997** for application number **1997-34**.

For the Respondent

RULING

1. **The Applicant**

   Rev. Stephen Elliot, Pastor, Kanata Wesleyan Church, is a person who has received a permit under the *Building Code Act, 1992* to renovate an existing worship building known as Kanata Wesleyan Church, City of Kanata, Ontario.

2. **Description of Construction**

   The Kanata Wesleyan Church is a two storey building made of combustible construction. The building does not have a sprinkler system, nor a standpipe and hose system. It is equipped with a fire alarm system. The building's area is 644.5 m2 (6 937 ft2). It is classified as having a Group A, Division 2 as its major occupancy.

3. **Dispute**

   The issue under dispute between the Applicant and the Respondent is whether the stairs to the chancel platform should be considered an access to an exit and therefore would require the installation of handrails in accordance with Sentence 3.4.6.4.(1) of the 1990 Ontario Building Code.

4. **Provisions of the Building Code**

3.4.6.4. Handrails

(1) Every *ramp* or stairway shall have a handrail on at least one side, and where 1 100 mm (3 ft 7 in) or more in width, shall have handrails on both sides.

5. **Applicant's Position**

The Applicant submitted that the renovated stairs serving the chancel platform should be considered as "access to exit" and not "exit" stairs. In their opinion, Sentence 3.4.6.4.(1) only applies if the subject stairs are defined as exit stairs. As they point out, if there were an exit located in the chancel area, then they could be considered as exit stairs. However, there is no such exit. The Applicant also argues that traditionally handrails serving chancel or podium areas have not been required in churches and other worship buildings.

6. **Chief Building Official's Position**

The Respondent submitted that the proposed chancel stair renovation is subject to Sentence 3.4.6.4.(1). It is their view that the stairs at issue are exit stairs serving the chancel platform. Even if they were considered as "access to exit" stairs, they argue that handrails would still be necessary. Further, as per Sentence 3.4.6.4.(1), because the stairs are wider than 1 100 mm, two handrails are required.

7. **Commission Ruling**

It is the decision of the Building Code Commission that the stairs demonstrate sufficiency of compliance provided a handrail is installed on one side of each staircase.

8. **Reasons:**

1. The stairs are used primarily during church services by a limited number of people, typically the pastor and musicians.

2. The stairs are well lit by overhead lights and natural light from windows.

3. The stairs contain a limited number of risers.

4. Evidence was presented that stairs serving chancel platforms have historically been built without handrails.

RULING

1. **The Applicant**

   Mr. Bill Laurysen, Vice President, Laurysen Kitchens Ltd., is a person who has applied for a permit under the *Building Code Act, 1992* to renovate and add to an existing kitchen manufacturing and storage facility. The existing building is 1 storey, constructed of noncombustible material and faces three streets. The area of the existing structure was 3 849 m2 (41 427 ft2) before the addition. The building does not have a sprinkler system, a fire alarm system, nor a standpipe and hose system. It is classified as having a Group F, Division 2 major occupancy.

2. **Description of Construction**

   The building addition adds 954 m2 (10 272 ft2) of additional space to the building. Most of this area is devoted to storage. Also part of these renovations is a spray painting booth having an area of 68 m2 (729 ft2). With these additions, the total building area is 4 803 m2 (51 699 ft2).

   The Applicant proposes to sprinkler the new spray booth area. As well, they would provide it with an additional dust collector piping system.

   The proposal also intends to address a previous work order regarding certain fire safety deficiencies, in particular, the lack of a required standpipe and hose system and adequate water

supply at the subject site. This would be accomplished by installing a fire alarm and detection system, self-closure devices on electrical room doors, and portable fire extinguishers throughout the building. The Applicants also propose to fill the on-site swimming pool and connect it to a hydrant for additional on-site water supply. They would also train their employees regarding fire safety.

3. **Dispute**

The issue under dispute between the Applicant and the Respondent is whether the renovations and additions provide sufficiency of compliance with the requirements to provide adequate water supply, a standpipe and hose system, and to sprinkler the spray booth in accordance with provisions 3.2.5.8., 3.2.9.1., and 6.2.2.5. respectively of the 1990 Ontario Building Code (OBC).

4. **Provisions of the Building Code**

3.2.5.8. Water Supply

(1) An adequate water supply for fire fighting shall be provided for every *building*.

(2) Hydrants shall be located within 90 m (295 ft 3 in) horizontally of any portion of a *building* perimeter which is required to face a street in Subsection 3.2.2.

3.2.9.1. (Standpipe and Hose System) Where Required

(1) Except as provided in Article 3.2.9.2., a standpipe and hose system hall (sic) be installed in every *building* that

(a) is more than

(i) 3 *storeys* in *building height*, or

(ii) 14 m (45 ft 11 in) in height measured between *grade* and the ceiling of the uppermost storey,

(b) is greater in *building area* than the area shown in Table 3.2.9.A. for the applicable *building height* shown in the table where the *building*

(i) is not *sprinklered*, and

(ii) is not more than 14 m (45 m [sic] 11 in) high measured between *grade* and the ceiling of the top *storey*, or

(c) contains more than one *storey* below *grade*.

6.2.2.5. Hazardous Gases, Dusts or Liquids

Systems serving spaces that contain hazardous gases, dusts or liquids shall be designed, constructed and installed in conformance with the provisions of the Ontario Fire Code made under the Fire Marshals Act, or in the absence of requirements pertinent to such systems in the Ontario Fire Code, to good engineering practice such as is described in the publications of the National Fire Protection Association and in the National Fire Code of Canada 1990.

5. **Applicant's Position**

The Applicant submitted that since there is no municipal water service to the site, the requirements to provide adequate on-site water supply and a standpipe and hose system are onerous and costly. They estimate that it would cost $187 200 to provide a standpipe system based on 68 000 L of water supply. The Applicant further argues that the alternative measures that they are offering would provide a higher level of fire safety than a standpipe and hose system.

It is the view of the Applicant, as represented by their agents, Morrison Hershfield, that they are improving the fire safety of the plant in several ways. They are proposing that a single-stage, supervised and monitored fire alarm and detection system be installed. This system, they argue, would provide immediate notification to the Township's fire department and early warning to the occupants. As the Applicant points out, for a building of this kind with an occupancy of only 50 people, such an alarm and detection system is not required.

They also propose to sprinkler the spray booth area in accordance with requirements of Ontario's Building and Fire Codes. This area would be provided with suppression protection by 8 sprinkler heads. A dust collector piping system would also be installed in the spray booth area as required by Section 5.10 of the Ontario Fire Code. This would provide spark detection and water spray fire suppression for the spray booth.

Dry chemical, portable fire extinguishers that can be used in multipurpose situations would also be installed throughout the plant's workshop areas.

In order to provide greater on-site water supply, the Applicant proposes to refurbish an unused indoor 200 000 L capacity swimming pool located elsewhere (approximately 47 m from the plant in the office building) on the Laurysen property. A wall hydrant would be connected to this water supply reservoir, and using a flow rate of 3 000 L/min, the Applicant believes this would provide a 1 h water supply.

Automatic closers on electrical service room doors and latches are also proposed by the Applicant to ensure that the room is fire separated from the rest of the plant.

As well, the Applicant intends to upgrade their fire safety plan. The employees at the plant will be given fire emergency training and will also be trained to effectively operate fire extinguishers. This too, they note, is also not required for a building with 100 occupants or less.

The Applicant believes the above measures would provide sufficiency of compliance with the OBC requirements for adequate water supply and a standpipe and hose system.

The Applicants also point out that the subject building is only one storey, with high ceilings, open structure, and it has good unobstructed access to exterior exits. They note that the building has good fire fighting access from three sides and would not be a hazard to other properties in the event of a fire. Furthermore, it is their view that the municipality provides more than sufficient fire fighting service.

6. **Chief Building Official's Position**

The Respondent submitted that the proposed renovations, while providing greater fire safety, still do not bring the building into compliance with Code requirements, especially concerning a standpipe and hose system. The building, they argue, is 2.4 times the maximum area at which a standpipe and hose system is required. Even without an expansion of the building, the original structure (Blocks 1 and 2 at 3 849 m2 [41 427 ft2]) is in need of a standpipe and hose system according to OBC Article 3.2.9.1. In their view, the proposed renovation creates even greater demand for such a system. Indeed, the proposed renovation would bring the building to the maximum size (4 800 m2 [51 700 ft2]) allowed for an unsprinklered structure of this nature. This unsprinklered limit assumes, however, that the building is equipped with adequate water pressure and a standpipe and hose system.

Whether the mezzanine has the appropriate fire resistance rating is also a concern for the Respondent.

Regarding the spray booth, the Respondent demonstrates that it is required to be sprinklered under the OBC and the OFC. Sprinklering this area, therefore, does not create additional fire safety

The Respondent further points out that the fire alarm and detection system would not be as useful as suggested by the Applicant since the municipality does not have the technical and administrative capacity to immediately notify its volunteer fire department.

Finally, the Respondent states that it is beyond the powers afforded to a CBO to judge whether the proposed measures provide sufficiency of compliance with the above referenced Code provisions.

7. **Commission Ruling**

It is the decision of the Building Code Commission that the building addition does not provide sufficiency of compliance with the requirements of the Building Code.

8. **Reasons:**

1. It is the opinion of the Building Code Commission that the proposals that were presented do not provide equivalent levels of life safety or property protection to those provided by the Building Code.

Dated at Ottawa this 3rd day in the month of July in the year **1997** for application number **1997-20**.

RULING

1. **The Applicant**

   Mr. John Russo has applied for a building permit under the *Building Code Act, 1992* to build a two-storey single-detached house at 68 Ellsworth Ave., Richmond Hill, Ontario.

2. **Description of Construction**

   The proposed two-storey single-detached house is 4338 square feet with unprotected openings amounting to 20.3% of the west building face.

3. **Dispute**

   The dispute between the Applicant and the Respondent concerns whether the proposed window openings on the west side of a 2-storey single-detached house provides sufficiency of compliance with Article 9.10.14.1. and Sentence 9.10.14.12.(4) of the Building Code.

4. **Provisions of the Building Code**

   Article 9.10.14.1. Maximum Percentage of Unprotected Openings

   (1) Except as provided in Sentence (2) and in Articles 9.10.14.3. to 9.10.14.11., the maximum percentage of unprotected openings in an exposing building face shall conform to Table 9.10.14.A. or Subsection 3.2.3., whichever is the least restrictive for the occupancy being considered.

   (2) An opening in an exposing building face not more than 130 cm2 (20 in2) shall not be considered an unprotected opening.

   Sentence 9.10.14.12.(4) Exposing Building Face of Houses

(4) Where the spatial separation between dwelling units on adjoining properties is registered on the titles of both properties, the spatial separation may be calculated as if the dwelling units were constructed on the same property.

5. **Applicant's Position**

The Applicant proposes to build the house with window openings totalling 20.3% of the west side building face instead of the 7.2% permitted by the Building Code. The land on the west side is vacant and is partly under a conservation flood zone. As well, the Applicant deems that there are certain building restrictions on title on the adjacent land which would preclude the erection of any structure.

6. **Chief Building Official's Position**

The Respondent deems that the Town has not been provided with information that Sentence 9.10.14.12.(4) has been satisfied. The Town's records indicate that the adjacent lands are not under a conservation flood zone but are designated as Residential under the Zoning By-law. Furthermore, these lands are not owned by the Town or any other public authority. As a result, Article 9.10.14.1. of the Building Code applies.

7. **Commission Ruling**

It is the decision of the Building Code Commission that the proposed window openings on the west side of a 2 storey single-detached residential dwelling do not provide sufficiency of compliance with Article 9.10.14.1. and Sentence 9.10.14.12.(4) of the Building Code.

8. **Reasons:**

There are a number of options to address the % openings in walls facing property lines such as

i) The use of Sentence 9.10.14.12.(4) of the Building Code, as follows:

(4) Where the spatial separation between dwelling units on adjoining properties is registered on the titles of both properties, the spatial separation may be calculated as if the dwelling units were constructed on the same property.

ii) The protection of openings by closures having a 1 hour fire resistance rating such as fire shutters.

iii) The installation of sprinklers or wired glazing in steel frames as outlined in 9.10.14.6. of the Building Code.

City of Etobicoke

RULING

1. **The Applicant**

   Mr. Angelo Villardo, Vice-President, Evan Mercury Sales Ltd., Etobicoke was issued a permit under the *Building Code Act, 1992* to extend and add an office to the existing mezzanine at 5500 Dundas Street West, Etobicoke, Ontario.

2. **Description of Construction**

   The existing building is one storey made of non-combustible construction with a building area of 23,000 square feet (2,137 square metres) under a Group F, Division 2 major occupancy. The proposed construction is to add 867 square feet (81 square metres) to the 2,007 square feet (184 square metres) existing mezzanine by extending onto the existing roof of the building.

3. **Dispute**

   The dispute between the Applicant and Respondent concerns whether the proposed extension may be considered as part of a mezzanine under the Building Code.

4. **Provisions of the Building Code**

   Sentence 3.2.1.1.(3) - Mezzanine with Open Floor Area

(3) Except as provided in Sentences (4), (5) and (8), a mezzanine shall not be considered as a storey in calculating the building height provided
(a) the aggregate area of the mezzanine floor is not more than 40 percent of the area of the room or storey in which it is located,

(b) it is used as an open floor area except as provided in Sentence 3.3.2.11.(2), and

(c) the space above the mezzanine floor has no visual obstructions more than 1 070mm (3 ft 6 in) above such floors.

Sentence 3.2.1.1.(4) - Mezzanine with Visual Obstructions

(4) Except as provided in Sentence (5), a mezzanine shall not be required to be considered as a storey in calculating building height and need not conform to Sentence (3) where the aggregate area of the mezzanine floor does not exceed 10 per cent of the area of
(a) the suite in which it is located, where there is more than one suite in the storey, or

(b) the storey in which it is located, in all other cases.

5. **Applicant's Position**

In the proposed addition, the Applicant based the design on Clause 3.2.1.1.(3)(a) of the Building Code where the aggregate area of a mezzanine can be up to 40% of the storey in which it is located. The Applicant deemed that the aggregate area of the existing and new mezzanine area amounts to 2,871 sq. ft. or 12.5% of the total storey.

6. **Chief Building Official's Position**

The Respondent indicated that the mezzanine has a visual obstruction that does not satisfy the requirements of Sentence 3.2.1.1.(3) of the Building Code and therefore Sentence 3.2.1.1.(4) applies. With the addition, the total floor area exceeds 10% of the area of the main floor, thus exceeding the allowable limit under Sentence 3.2.1.1.(4) of the Building Code. Therefore, the addition cannot be considered as part of the mezzanine and must be designed as a second floor.

7. **Commission Ruling**

It is the decision of the Building Code Commission that the approximate 450 sq. ft. addition over the roof provides sufficiency of compliance with the Building Code provided that a fire

separation with wired glazing having a 3/4 hour fire resistance rating separates the new corridor from the existing mezzanine area.

8. **Reasons:**

i) The mezzanine area addition of 450 sq. ft. has direct access to the roof and then to grade.

ii) The mezzanine area addition will have access to the existing mezzanine area and the two exits from that area.

iii) The increased area of 450 sq. ft. represents approximately 2% of the total 1st floor area.

iv) The Commission is of the opinion that this addition does not present an undue risk to life safety from fire due to the additional exit and fire separation.

For the Applicant

Mr. John Miller
Chief Building Official
Town of New Tecumseth
For the Respondent

RULING

1. **The Applicant**

   Mr. Nisio Rizzardo, Manager, Previn Court Homes, is a person who has applied for a permit under the *Building Code Act, 1992* to build residential dwellings with slab-on-ground construction for the basement foundations at Lots 81,92 and 97 of Plan 51M-488 and Lot 52 of Plan 51M-413, Town of New Tecumseth, Ontario.

2. **Description of Construction**

   The proposed single-detached residential buildings are 1 and 2 storeys, and are classified as Group C Residential under the OBC. The subject building areas would range from 1,200 to 1,800 ft2. The proposed structures are to be made of combustible construction.

   Uninsulated concrete slab-on-ground foundations are proposed for the basement area of each building.

3. **Dispute**

   The issue under dispute between the Applicant and the Respondent is whether the proposed concrete slab-on-ground construction should be insulated to a minimum thermal resistance rating of R8 according to Sentence 9.25.2.7.(1) and Table 9.25.2.A. of the 1990 Ontario Building Code.

4. **Provisions of the Building Code**

   9.25.2.6. Insulation around Concrete Slabs-on-Ground

Insulation around concrete slabs-on-ground shall extend not less 600 mm below exterior ground level.

9.25.2.7. Minimum Thermal Resistance

(1) Except as permitted in Sentences (2), (3) and (4) the minimum thermal resistance of insulation shall conform to Table 9.25.2.A.

5. **Applicant's Position**

The Applicant submitted that the proposed concrete slab-on-ground construction proposed for the subject residential dwellings should not be required to conform to the thermal resistance rating specified in Table 9.25.2.A. As they note, the slab-on-ground floor proposed for each type of residential building on all lots will be located 2.4 m (8 ft.) below the exterior grade level. In their opinion, because the subject slabs-on-ground are lower than the 600 mm depth specified in Article 9.25.2.6. no insulation is therefore required.

The applicants also cite Subsection 9.38.3., Thermal Resistance of Assemblies, specifically Article 9.38.3.7., which sets out the alternative requirements for insulation applied to the exterior of a slab-on-ground floor. It states that insulation is required to be applied to the exterior of the slab-on-ground also to a depth of 600 mm. Thus, it is their belief that the OBC does not require the proposed slabs-on-ground to be insulated.

6. **Chief Building Official's Position**

The Respondent submitted that as per Article 9.25.2.1 of the OBC all walls that separate heated space from exterior soil are required to be insulated. They noted that the plans submitted by the applicant show habitable space in the basement levels. As a result, in their opinion, the proposed slabs-on-ground are required to comply with Sentence 9.25.2.7.(1). As such, they are to be built with a thermal resistance rating of R8 according to Table 9.25.2.A.

7. **Commission Ruling**

It is the decision of the Building Code Commission that the non insulated basement floor slabs which are located 2.5 m below ground in the subject buildings comply with the Building Code.

8. **Reasons:**

It is the intent of the Building Code that only the finished concrete floors of the lowest level of a building constructed within 600 mm below exterior ground is required to have thermal insulation.

RULING

1. **The Applicant**

   Mr. John Ward, Owner, Country Produce Orillia Ltd., is a person who has applied for a permit under the *Building Code Act, 1992* to renovate an existing commercial retail facility by constructing an addition on the east side of the building at Country Produce Orillia Ltd., City of Orillia, Ontario.

2. **Description of Construction**

   The existing retail facility is described as a 1 storey building, facing 2 streets, constructed mostly from noncombustible material. Fifteen percent of the existing building has a combustible roof structure. The building is classified as a Group E, mercantile occupancy under the OBC. The area of the existing building is 1,302 m2. The structure does not have a fire alarm system, a standpipe and hose system, nor a sprinkler system. It is currently being used as a fresh produce retail outlet.

   The applicant proposes to attach a 1 storey, 280 m2 addition to the existing building. The total area of the proposed structure would be 1,582 m2. They are not proposing to include sprinklers throughout the facility as a result of this construction.

3. **Dispute**

The issue under dispute between the Applicant and the Respondent is whether the proposed enlarged building, without sprinklers, provides sufficiency of compliance with Article 3.2.2.44. of the 1990 Ontario Building Code. The renovated building would exceed the allowable floor area for an unsprinklered, 1 storey mercantile building, facing 2 streets by 86 m2. (The area allowable under Article 3.2.2.44. is 1,496 m2, while the renovated structure they are proposing would be 1,582 m2.)

4. **Provisions of the Building Code**

3.2.2.44. Mercantile Buildings, up to 3 Storeys

(1) A building classified as Group E shall conform to Sentence (2) provided the building
(a) is not more than 3 storeys in building height, and

(b) has a building area not more than the value in Table 3.2.2.M.

(2) The building shall be of combustible or non-combustible construction used either singly or in combination, and
(a) floor assemblies shall be fire separations with a fire-resistance rating of not less than 45 min,

(b) mezzanines shall have, if of combustible construction, a fire-resistance rating of not less than 45 min,

(c) roof assemblies shall have a fire-resistance rating of not less than 45 min, except that in buildings not more than 1 storey in building height, the fire-resistance rating is permitted to be waived provided the roof assembly is of noncombustible construction or is constructed as a fire-retardant treated wood roof system conforming to Article 3.1.14.1., and

(i) if unsprinklered, the building area is not more than 1 500 m2 (16,100 ft2), and

(ii) if sprinklered, the building area is not more than 2 400 m2 (25,800 ft2) if facing 1 street,

3 000 m2 (32,300 ft2) if facing 2 streets, or

3 600 m2 (38,800 ft2) if facing 3 streets,

(d) all loadbearing walls, columns and arches supporting as assembly required to have a fire-resistance rating shall have a fire-resistance rating of not less than 45 min or shall be of noncombustible construction, except that such members and assemblies supporting a fire separation shall have a fire-resistance rating not less than that required for the supported assembly.

5. **Applicant's Position**

The Applicant submitted that the proposed renovation of the Country Produce Orillia building should be considered as providing sufficiency of compliance with Article 3.2.2.44. As they note, the combined area of the expanded building will be only 86 m2, or 5.75% over the maximum building area allowed without sprinklers. They also point out that the occupant load is relatively low. In addition, only approximately 60% of the building is open to the public, meaning that the sizeable rear portion of the structure has an even lower occupant load. As well, all exits are at grade enabling quick evacuation and good fire fighting access.

The applicants argue that it is impractical to install a sprinkler system due to construction difficulties and a lack of adequate water supply service. To mitigate the absence of sprinklers, it is proposed that an interconnected smoke detection system be installed in the non-public areas of the building.

6. **Chief Building Official's Position**

The Respondent submitted that the proposed renovation would enlarge the subject building beyond the allowable unsprinklered limit as set out in Article 3.2.2.44. They concur with the applicant regarding their rationale that the expanded Country Produce Orillia structure would provide sufficiency of compliance with the OBC, however, they believe they do not have the authority to accept such a proposal.

7. **Commission Ruling**

It is the decision of the Building Code Commission that the proposed addition provides sufficiency of compliance with Article 3.2.2.44 without sprinklers provided that 1) that interconnected smoke alarms are installed in the staff/support areas of the building, and 2) that work area is separated from the remainder of the building by a 1 hour fire separation through the installation of closures having a 45 min. fire protection rating.

8. **Reasons:**

i) The total area of the building in this category requiring sprinklers is only 87 m2 or approximately 6% above the maximum area.

ii) Increased early warning detection and alarm is provided in the building.

iii) The building is a single storey with no basement with access for fire fighting directly at grade from three access routes.

iv) The addition is non combustible construction.

v) The building is subdivided by separation having a 1 hour fire protection rating.

Dated at Toronto this 12th day in the month of June in the year **1997** for application number **1997-33**.

RULING

1. **The Applicant**

   Mr. John Van Oostrom, Principal Civil Engineer, DuPont Canada Inc., is a person who has applied for a permit under the *Building Code Act, 1992* to renovate an existing nylon manufacturing plant by constructing an addition on the south-east corner of the building at DuPont Canada Inc., Township of Kingston, Ontario.

2. **Description of Construction**

   The DuPont Canada facility at Kingston has been renovated several times since it was built in 1941. The existing building area is 61,700 m2. Most of this area is 1 storey however the east side is several levels in height. The subject building has a fire alarm system, a standpipe and hose

system, and is partially sprinklered. There is also a fire protection main system that encircles the entire building. This includes 20 hydrants on the inside, around the perimeter and on the roof. The fire alarm system and sprinkler system are monitored 24 hours a day.

The Kingston DuPont plant was renovated in 1992 and 1993 to add a nylon spinning facility. Known as the BCF-93 Addition, the spinning facility was constructed on the south-east corner of the original plant. The BCF-93 Addition was deemed to be a separate building since a fire wall was built between it and the existing structure. It was constructed in accordance with Article 3.2.2.57. which allows unrated noncombustible construction. The 1993 addition included a full sprinkler system (electronically supervised) and a standpipe and hose system.

Since there is generally a low fire load in the BCF-93 Addition, the Township at the time classified it as a Group F, Division 3 low hazard industrial occupancy. There are seven levels in the existing BCF area, however, all levels above the ground floor are service platforms and are nearly unoccupied, except for two people on the second level.

The subject renovation proposes to further expand the BCF-93 Addition. The new area will also be noncombustible construction. All of the fire safety systems will be included in the extended building.

With this new addition, the BCF facility would have a total occupant load of 32 persons (27 on the ground floor, 3 on the second and 2 on all other upper levels combined) and would have fire vehicle access routes on 3 sides, covering 70% of the building's perimeter. A further addition, known as the New Quality Area, is to be constructed simultaneously on the west side of the existing BCF-93 Addition and will provide new shipping and warehousing capacity. This area is not under dispute.

3. **Dispute**

The issue under dispute between the Applicant and the Respondent is whether the proposed addition is to be considered 1 or 4 storeys in building height. Sentence 3.2.1.1.(8) of the 1990 Ontario Building Code provides exceptions when calculating building height in storeys. If the proposed addition does not comply with Sentence 3.2.1.1.(8) and is found to be 4 storeys in building height then the renovation cannot be constructed in accordance with OBC Article 3.2.2.57. Further, the proposal may also exceed the allowable maximum building area under 3.2.2.57.

4. **Provisions of the Building Code**

3.2.1.1. Exceptions to Building Height in Storeys

(8) *Mezzanines*, elevated walkways and platforms in Group F, Division 2 or 3 *major occupancies* need not be considered as *storeys* in calculating *building height* provided

(a) the *building* is of *noncombustible construction*,

(b) except for Clause (c), the *mezzanines*, elevated walkways and platforms are intended solely for periodic service and maintenance, and

(c) where they are intended to be occupied, no *mezzanine*, elevated walkway or platform shall have an *occupant load* more than 4 persons.

3.2.2.57.Industrial Buildings, Division 3, up to 4 Storeys

(1) A *building* classified as Group F, Division 3 shall conform to Sentence (2) provided the *building*

(a) is not more than 4 *storeys* in *building height*

(b) if unsprinklered, has a *building area* not more than the value in Table 3.2.2.57., and

(c) if *sprinklered*, is not more than twice the area limits of Clause (b).

(2) The *building* shall be of *combustible* or *noncombustible construction* used either singly or in combination, and

(a) floor assemblies shall be *fire separations* and, if of *combustible construction*, shall have a *fire-resistance rating* of not less than 45 min,

(b) *mezzanines* shall have, if of *combustible construction*, a *fire-resistance rating* of not less than 45 min,

(c) roof assemblies shall have, if of *combustible construction*, a *fire-resistance rating* of not less than 45 min, except that in *buildings* not more than 1 *storey* in *building height*, the fire-resistancerating of not less than 45 min, except that in *buildings* not more than 1 *storey* in *building height*, the fire-resistance rating is permitted to be waived provided that the roof

assembly is constructed as a *fire-retardant treated wood* roof system conforming to Article 3.1.14.1., and

(i) if unsprinklered, the *building area* is not more than

2 400m2 (25,800 ft2) if facing 1 *street*,

3 000m2 (32,300 ft2) if facing 2 *streets*, or

3 600m2 (38,800 ft2) if facing 3 *streets*, and

(ii) if *sprinklered*, the *building area* is not more than twice the area limits of Subclause (i), (see Article 3.2.2.12. for supervised sprinkler systems) and

(d) all *loadbearing* walls, columns and arches supporting an assembly required to have a *fire-resistance rating* shall have a *fire-resistance rating* of not less than 45 min or shall be of *noncombustible construction*.

5. **Applicant's Position**

The Applicant submitted that the proposed renovation of the BCF area could be considered a 1 storey addition in building height. They believe that the proposal meets the criteria found in Sentence 3.2.1.1.(8). As they note, the BCF area, will be all noncombustible construction. The upper levels will only be used for periodic service and inspections, and the occupant load on the second level will be 2 persons, lower than the 4 allowed.

Even though, as the applicant argues, none of the upper levels need to be regarded as storeys, the applicant is proposing that the renovated BCF facility be considered a 2 storey building. This would allow DuPont some flexibility in the future for staffing the second level. The 4,080m2 area of the extended BCF facility, they note, would still fall well below the 7,200m2 allowed under Article 3.2.2.57. for a 2 storey building facing 2 streets.

6. **Chief Building Official's Position**

The Respondent submitted that the proposed renovation is 4 storeys in building height. As such, the structural fire-resistance provisions under OBC Article 3.2.2.57. do not apply. They point out that 3 of the upper levels are made of solid concrete construction and cover 100% of the building area. As such, they should be viewed as storeys.

Further, they believe the building exceeds its allowable area. Assuming the building faces 3 streets, they calculate (based on full sprinklering) that the maximum area allowed under 3.2.2.57. is 3,600 m2. In their belief, the proposed structure is approximately 13% over the allowable limit.

7. **Commission Ruling**

It is the decision of the Building Code Commission that the building is considered to be a two storey building with multiple level industrial platforms and complies with the requirements of Article 3.2.1.1 of the Building Code.

8. **Reasons:**

1) The building height is necessary for the manufacturing process and equipment.

2) The building is of noncombustible construction.

3) The industrial platforms are intended solely for periodic service and maintenance.

4) The occupant load of no elevated platform exceeds 4 persons.

The Respondent

RULING

1. **The Applicant**

   Mr. Stephen Roth, General Manager, Waterloo Stage Theatre, is a person who has applied for a permit under the *Building Code Act, 1992* to renovate an existing 500 seat cinema for live theatre productions. The building is 1 storey with a partial mezzanine at one end that had previously been used as a projection booth and a small basement for mechanical equipment. The building contains a fire alarm system and has sprinklers servicing the stage area.

2. **Description of Construction**

   The proposed renovation would erect a new stage. Across the rear portion of the stage would be a small open mezzanine space. The seating capacity would be reduced to 252. Some modifications are to be made to the existing projection booth to allow for light and sound control.

3. **Dispute**

The issue under dispute between the Applicant and the Respondent is whether the proposed performance area is a stage as defined by the 1990 Ontario Building Code (OBC) and whether the subject area is required to be designed in accordance with OBC Article 3.3.2.13.

4. **Provisions of the Building Code**

3.3.2.13. Stages for Theatrical Performances

1. *Stages* for theatrical performances and ancillary spaces, such as workshops, dressing rooms and storage areas shall be *sprinklered*.
2. A *fire separation* with a *fire-resistance rating* of not less than 1 h shall be provided between every *stage* for theatrical performances and ancillary spaces, such as workshops, dressing rooms and storage areas.
3. Every *stage* for theatrical performances and ancillary spaces, such as workshops, dressing rooms, and storage areas, shall be separated from the seating space by a *fire separation* having a *fire-resistance rating* of not less than 1 h, except for a proscenium opening which shall be protected with

   (a) a sprinkler deluge system conforming to the requirements of paragraph 4-4.20 of NFPA 13 "Standard for the Installation of Sprinkler Systems",
   (b) an unframed fire curtain when the opening is not more than 20 m (65 ft 7 in) wide, or
   (c) a semi-rigid fire curtain when the opening is more than 20 m (65 ft 7 in)

4. Every fire curtain as required by Sentence (3) shall be designed to close

   (a) automatically by heat-actuated devices,
   (b) automatically upon the actuation of the sprinkler system,
   (c) automatically upon the actuation of the fire alarm system, and
   (d) manually by remote control devices located at the curtain control panel and at each side of the *stage*.

5. Not less than 2 vents for the purpose of venting fire and smoke to the outside of a *building* shall be provided above every *stage* designed for theatrical performances and shall

   (a) have an aggregate area of not less than one eighth of the area of the *stage* behind the proscenium opening, and

(b) be arranged to open automatically by means of

(i)heat-actuated devices, or

(ii) actuation of the sprinkler system.

1.1.3.2. Definitions of Words and Phrases

Stage means a space designed primarily for theatrical performances with provision for quick change scenery and overhead lighting, including environmental control for a wide range of lighting and sound effects and which is traditionally, but not necessarily, separated from the audience by a proscenium wall and curtain opening.

5. **Applicant's Position**

The Applicant submitted that the performance area of the Waterloo Stage Theatre does not meet the OBC definition of a stage. Accordingly, they believe the provisions of Article 3.3.2.13. should not apply. This view is based on the fact that while the subject stage does include lighting equipment, it does not contain facilities to provide quick change scenery, especially side stages, a fly tower and accompanying equipment. The lack of these facilities means that ancillary space is limited and any fire would be quite noticeable by the audience. Further, the exit capacity is approximately double the occupant load, the farthest travel distance is 20 m, and the stage is currently sprinklered.

6. **Chief Building Official's Position**

The Respondent submitted that the proposed performance area should be considered a stage under the OBC and therefore should be designed to meet the full requirements of Article 3.3.2.13. As a result the stage should include 1 h rated proscenium opening, either a "fire curtain" or deluge sprinkler system, and a fire and smoke venting system.

7. **Commission Ruling**

It is the decision of the Building Code Commission that the stage provides sufficiency of compliance to the requirements of the Building Code provided:

1. quick response sprinklers are installed over the stage and ancillary areas,
2. smoke detection, connected to an alarm system, is installed over all stage areas including the ancillary room at the rear of the stage and below the mezzanine area, and

3. the area under the stage is sealed such that it cannot be used for storage.

8. **Reasons:**
    1. The theatre, stage and back of the house areas are of limited size.
    2. The theatre has limited seating capacity.
    3. A sprinkler system will be provided.
    4. Adequate exits will be provided.
    5. The maximum travel distance does not exceed 20 m.
    6. There are no provisions for quick change scenery or fly towers, which limits the combustible load on the stage.

Dated at Toronto this 28th day in the month of May in the year **1997** for application number **1997-19**.

RULING

1. **The Applicant**

   Mr. Greg Gaudette, Property Manager, Shoppers World Company Inc., is a person who has applied for a permit under the *Building Code Act, 1992* to renovate an existing shopping mall by constructing additional retail units on one side of a 12.5 m (41 ft) wide public corridor at Shoppers World Albion, Etobicoke, Ontario.

2. **Description of Construction**

   The Shoppers World Albion mall is a noncombustible 1 storey building with a building area of 356,000 sq. ft. (33,073 sq. m.). The subject building has a fire alarm system, an automatic sprinkler system, and a standpipe and hose system.

   The proposed interior renovation is to construct additional retail units on one side of the existing 12.5 metre wide public corridor adjacent to the K-Mart Store at the east end of the shopping centre.

3. **Dispute**

The issue under dispute between the Applicant and the Respondent is whether the proposal meets the intent of Sentence 3.3.1.9. (6) of the 1990 Ontario Building Code (OBC) which requires that occupancies in a public corridor be located in such a manner that there is an unobstructed passage for pedestrian travel of specified widths adjacent and parallel to all rooms and suites that front onto the public corridor, and that the combined area of all occupancies in a public corridor shall not exceed 15% of that area. Also under dispute is whether Clause 3.4.2.5. (1)(d) of the OBC, regarding the location of exits served by a public corridor, may be applied.

4. **Provisions of the Building Code**

3.3.1.9. Corridors

(6) If a public corridor conforming to Clause 3.4.2.5.(1)(d) contains an occupancy, the occupancy shall be located so that there is an unobstructed width for pedestrian travel of not less than 3 m (9 ft 10 in) adjacent and parallel to all rooms and suites that front onto the public corridor and the combined area of all occupancies in a public corridor shall not be more than 15 percent of the area of the public corridor.

3.4.2.5. Location of Exits

(1) Except as provided in Sentences (2), (3) and 3.3.2.4.(6), where more than one exit is required from a floor area, such exits shall be located so that the travel distance to not less than one exit as described in Article 3.4.2.4. shall be not more than
(d) 105 m (344 ft 6 in) in any floor area, served by a public corridor, in which rooms and suites are not separated from the remainder of the floor area by a fire separation, provided
(i) the public corridor has a width of not less than 9 m (29 ft 6 in),

(ii) the ceiling height in the public corridor is not less than 4 m (13 ft 1 in) above all floor surfaces,

(iii) the building is sprinklered, and

(iv) not more than one half of the required egress doorways from a room or suite open into the public corridor when the room or suite is required to have more than one egress doorway.

5. Applicant's Position

The Applicant submitted that the proposed renovation would still leave the subject public corridor in compliance with OBC requirements. Their view, as expressed in the report by Morrison Hershfield consultants, is that the width of the corridor should be calculated as 9 m, since the extra 3.5 m strip immediately adjacent to the K-Mart Store's wall may, according to the Code, be used as retail without contravening any provisions. They further argue that in a corridor of this length (146 m), a 9 m wide corridor is permitted to have additional occupancies provided that these occupancies do not exceed 15% of the area and that they are placed so as to allow for a 3 m unobstructed pedestrian passageway adjacent and parallel to the fronting rooms and suites. (They calculate 15% of the subject public corridor to be 197.1 sq. m.) It is their position that the Code does not prevent them from adding this additional retail area to the area directly abutting the K-Mart wall. In essence, they believe the Code does not prevent them from placing their additional 15% occupancies adjacent to, and beyond the 9 m line, as long as the corridor remains at least 6 m wide to allow for 3 m of unobstructed pedestrian width to serve the retail rooms and suites that face each other on either side of the corridor.

The Applicant also submits that the performance level of the building will not be reduced, including the access to exits. This is because the building contains both an early warning system, and a sprinkler system, and would thereby satisfy the compliance alternatives.

6. **Chief Building Official's Position**

The Respondent submitted that the Code does not intend public corridors to be less than 9 m in width. They calculate that by adding 197.1 sq. m. as additional retail space to the 3.5 m strip directly adjacent to the K-Mart Store the public corridor would be thus reduced to 7.6 m. Their position is that the Code allows some flexibility concerning additional occupancies as long as the corridor is, among other things, at least 9 m wide and that the extra occupancies are located "within" the corridor. In their view, the proposed renovation, by joining the additional occupancies to the one side and not placing them somewhere in the middle of the public corridor, will, in effect, reduce the corridor width.

7. **Commission Ruling**

It is the decision of the Building Code Commission that the minimum unobstructed public corridor width of 9 m must be provided as required to permit a distance of travel 105 m as noted in Clause 3.4.2.5.(1)(d) of the Building Code.

The occupancy permitted in the public corridor must be installed as per 3.3.1.9.(6) of the Building Code.

8. **Reasons:**
   i. A minimum clear width of 9 m is required to permit the 105 m travel distance to be applied.
   ii. The corridor occupancy as permitted in 3.3.1.9.(6) is intended to allow displays, kiosks and other similar obstructions in the centre of a minimum 9 m wide public corridor leaving 3 m of clear space on each side of the public corridor for pedestrian movement.
   iii. The 15% area limit is set to limit and control fire loads in the public corridor. This proposal does not satisfy this principle.
   iv. Other design configurations are available to meet the Building Code requirements.
   v. It is the opinion of the Building Code Commission that the proposal reduces the level of safety for the occupants and the property from fire.

The Applicant

RULING

1. **The Applicant**

   Mr. Konstantine Lamberis, Home Owner, 332 Pacific Avenue is a person who has been issued an Order to Comply under the *Building Code Act, 1992* to build a staircase in a single unit house at 332 Pacific Avenue, Toronto, Ontario.

2. **Description of Construction**

   The new stair was constructed to gain access to a newly conducted third floor attic space.

3. **Dispute**

   The issue under dispute between the Applicant and the Respondent is whether the new stair with a 2' 2" width rather the minimum required 2' 10" provides sufficiency of compliance with the Building Code.

4. **Provisions of the Building Code**

   Sentence 9.8.3.3.(2) Stair Width

   At least 1 stairway between each floor level in a dwelling unit shall have a minimum width between wall faces of not less than 860 mm (2' 10").

5. **Applicant's Position**

The Applicant submitted that the renovation of a house to add new stairs to the third floor will improve the means of egress from the second floor, that renovating to change the building from a rooming house to a single family dwelling will not reduce the level of safety, and that the space available in the existing 90 year old victorian house is limited.

6. **Chief Building Official's Position**

The Respondent submitted the stair up to the third floor level must have a minimum width of 2' 10" under Sentence 9.8.3.3.(2) of the Building Code as opposed to the 2' 2" as built.

7. **Commission Ruling**

It is the decision of the Building Code Commission that the existing stair from the 2nd to the 3rd floor having a minimum width of 2' 2" provides sufficiency of compliance with Sentence 9.8.3.3.(2) of the Building Code.

8. **Reasons:**

i) The stair services a small floor area with limited occupant load.

ii) The actual width is approximately 2" less than permitted under Part II.

iii) The third floor will have access to an exterior balcony.

iv) The stair will comply with all other dimensional requirements under the Building Code.

v) The building is being converted from a rooming house to a single family unit increasing the performance level.

RULING

1. **The Applicant**

   Mr. John Bate, President, John Bate & Co. Ltd. is a person who has applied for a permit under the *Building Code Act, 1992* to construct a freezer warehouse at Atlas Cold Storage Vaughan Limited, Vaughan, Ontario.

2. **Description of Construction**

   The subject building is a one storey freezer warehouse of F2 major occupancy with a building area of 5,495 square metres (59,148 sq ft). The unsprinklered building is of non-combustible construction and is to be held at a continuous temperature of (-20 degrees F).

3. **Dispute**

   The issue under dispute between the Applicant and the Respondent is whether the building is required to have access panels for fire fighting purposes adjacent to the fire routes on the east and north sides of the building in accordance with Article 3.2.5.1.

4. **Provisions of the Building Code**

3.2.5.1. Access to Above Grade Storeys

(1) Except for storeys below the first storey, direct access for fire fighting shall be provided from the outdoors to every storey having its floor level less than 25 m (82 ft) above grade by not less than one unobstructed window or access panel for each 15m (49 ft 3 in) of wall in each wall required to face a street in Subsection 3.2.2.

5. **Applicant's Position**

The Applicant submitted that it is impractical to place access panels every 15 metres around the perimeter of the building for fire fighting because: vandals would be able to enter the building; access to the panels would be blocked by contents of the warehouse; openings would increase the risk of vapour entry in the freezer; and, dimensions for the height of the sill imply that windows were presumed to be part of the structure which does not apply to a freezer warehouse.

6. **Chief Building Official's Position**

The Respondent submitted that Article 3.2.5.1. requires access to the first storey of this building for fire fighting purposes every 15 metres along the faces of the building adjacent to the fire route. The Chief Building Official also submitted that the Applicant has not proposed any alternative measures.

7. **Commission Ruling**

It is the decision of the Building Code Commission that the building provides sufficiency of compliance with Sentence 3.2.5.1.(1) and (2) of the Building Code on the conditions that;

i. A fire alarm system conforming to 3.2.4. of the building is installed with fire, heat or smoke detection throughout the freezer and the system shall be designed to notify the fire department as required by 3.2.4.7. of the Building Code.

8. **Reasons:**

i. The fire alarm system and central connection to the fire department will increase notification of a fire condition in the building and reduce fire department response.

ii. Although not conforming to the specific locations for access for fire fighting outlined in 3.2.5.1.(1) and (2) access is available from the exterior on 3 sides and from the loading dock to the south.

iii. The occupant load of the building is low (2 - 6) persons.

iv. The low operating temperatures (-20 degrees F) may have an effect in reducing the development of fire growth.

The Respondent

RULING

1. **The Applicant**

   Ms Fung Ching Chang, owner, is a person to whom an Order to Comply was issued under the Building Code Act, 1992 to remove a circular stair, at 196 Carolbreen Square, Scarborough Ontario.

2. **Description of Construction**

   The subject building is a 2 storey house with a building area of 167 square metres (1800 sq ft). A spiral stair with a run less than 150 mm has been installed between the basement and the first floor.

3. **Dispute**

   The dispute between the Applicant and the Respondent concerns sufficiency of compliance with Article 9.8.5.2. of the Ontario Building Code. At issue is whether the run on the spiral stair provides sufficiency of compliance with the Building Code.

4. **Provisions of the Building Code**

   9.8.5.2. Curved Stairs not in Exits

Except as permitted in Article 9.8.5.3., a curved stair not required as an exit shall have an average run of not less than 200 mm (7 7/8 in) and a minimum run of 150 mm (5 7/8 in) and shall have risers conforming to Article 9.8.3.1.

5. **Applicant's Position**

The Applicant submitted that the basement is a walkout basement and has a patio door which serves as the main exit, and that there is an additional exterior stair from the basement to another patio door serving the main floor level. The Applicant further submitted that the stair has been in use for more than one year.

6. **Chief Building Official's Position**

The Respondent submitted that the spiral stair was installed instead of a curved stair as noted on the original permit drawings, and that the spiral stair does not meet the requirements of 9.8.5.2. because the stair run at the narrow end is tapered to significantly less than the minimum required 150 mm. The Respondent further submitted that while there are ample exits from each floor the spiral stair is the only internal connection between the basement and main floor.

7. **Commission Ruling**

It is the decision of the Building Code Commission that the installed spiral stair which is not required as an exit, does not comply with the requirements of Article 9.8.5.2. of the Building Code.

8. **Reasons:**

i) The stair is the only interior communicating stair from this basement to the first floor.

ii) Non complying stair geometry may impose an increased likelihood of injury.

iii)No alternatives were proposed for sufficiency of compliance.

For the Respondent

RULING

1. **The Applicant**

   Mr. Fred C. DeNure is a person to whom an Order to Comply has been issued under the Building Code Act, 1992 to rectify an accessory building constructed at 60 Bond Street West, Lindsay, Ontario.

2. **Description of Construction**

   The subject building is a single storey accessory building of approximately 46 square metres (490 sq ft) of combustible construction located at the rear of the residential property which contains a detached residential dwelling.

3. **Dispute**

   The issue under dispute is whether the building is to be considered a separate building, and whether the combustible roof overhang which extends to within .483 metres (1 ft 7 in) of the north lot line is permitted under the Building Code.

4. **Provisions of the Building Code**

   9.10.14.13. Combustible Projections

Except for buildings containing 1 or 2 dwelling units only, combustible projections on the exterior of a wall that are more than 1 m (3 ft 3 in) above ground level, such as balconies, platforms, canopies, eave projections and stairs, and that could expose an adjacent building to fire spread, shall not be permitted within 1.2 m (3 ft 11 in) of a property line or the centreline of a public way, or within 2.4 m (7 ft 10 in) of a combustible projection on another building on the same property.

5. **Applicant's Position**

The Applicant submitted that 9.10.14.13. does not apply to this detached accessory building since it is an accessory building to a 1 or 2 dwelling structure. The Applicant further submitted that many municipalities also use this interpretation and allow accessory structures to have combustible projections closer to the lot line than allowed in 9.10.14.13.

6. **Chief Building Official's Position**

The Chief Building Official submitted that the building does not contain 1 or 2 dwelling units and therefore must comply with 9.10.14.13. and there is a no definition of an accessory building under the Building Code.

7. **Commission Ruling**

It is the decision of the Building Code Commission that the accessory building serving only a dwelling unit provides sufficiency of compliance with Article 9.10.14.13. of the Building Code.

8. **Reasons:**

i) Although not directly attached the building is a subsidiary use to the dwelling unit and may be considered as forming part of the dwelling unit.

ii) It is the opinion of the Building Code Commission that the building does not increase the risk to the property or adjacent property from fire.

RULING

1. **The Applicant**

   Mr. Al Carbone applied for a permit under the *Building Code Act, 1992* to renovate a restaurant at the Kit Kat Bar and Grill, 297 King Street West, Toronto, Ontario.

2. **Description of Construction**

   The subject building is 3 stories with restaurant uses on the ground floor and in the basement, and a single dwelling unit on the partial second and third floors. The building is approximately 96 square metres of combustible construction with no fire alarm or sprinkler systems.

3. **Dispute**

The issues under dispute are whether:

1- a change in major occupancy has occurred which may among other things, require the provision of a fire alarm and sprinkler system and,

2- wired glass skylights set in wood frames within 5 metres of an exterior wall, are permitted under Section 11.3. and Article 3.2.3.15. of the Building Code.

4. **Provisions of the Building Code**

11.3 Performance Level

3.2.3.15. Wall Exposed to Adjoining Roof

Except as permitted in Sentence 3.2.3.20.(4), where a wall in a building is exposed to a fire hazard from an adjoining roof of a separate unsprinklered fire compartment in the same building, and the exposed wall contains windows within 3 storeys verticall y and 5 m (16 ft 5 in) horizontally of such roof, the roof shall contain no skylights within 5 m (16 ft 5 in) of the exposed wall.

5. **Applicant's Position**

The Applicant submitted that the ground floor renovation to the restaurant was not a change in major occupancy and the hazard index need not be evaluated. The sprinkler protection and added fire separations required from a change in major occupancy are n ot necessary because:

- the occupants on the ground floor will be aware of the fire on the ground floor and have a choice of direction to 2 exists within 15 metres;

- occupants on the ground floor will be notified of a fire in the basement through a fire alarm and heat detection system;

- though not required, occupants of the second and third floor will also be notified of a fire on the ground floor through a fire alarm and detection system; and,

- if the ground floor was much larger and capable of accommodating a much higher occupant load, the building could be classified under a Group E major occupancy and not be required to have sprinkler protection.

6. **Chief Building Official's Position**

The Respondent submitted that based on a 1988 building permit and information from the Applicant in 1996 regarding the use of the building, the front of the building underwent a change in major occupancy from E to A2 and the rear of the building from an F3 to an A2. The Respondent indicated that such changes in major occupancy require the evaluation of the hazard index and the construction index. Based on such an evaluation the building would have a hazard index of 6. The Respondent further submitted that this hazard index would require the building to be of non-combustible construction, with 1 hour fire rated floors, 45 minute rated roofs, and a fire alarm system. Combustible construction is permitted with a 1 hour fire rating where the area is sprinklered. As well, fire resistance rating is not required on the roof and the skylight would only be permitted where the area below is sprinklered.

7. **Commission Ruling**

It is the decision of the Building Code Commission that the existing wood roof assembly with skylights of wired glazing in wood frame provides sufficiency of compliance with Section 11.3 and Article 3.2.3.15. of the Building Code provided that:

i) The exposed openings on the 2nd floor are protected with wired glass in fixed steel frames and;
ii) The fire alarm system is installed in accordance with Subsection 3.2.4. throughout the Building and;
iii) The means of egress from the 2nd and 3rd floor are protected from the first floor restaurant by a 3/4 hour fire separation.

8. **Reasons:**

i) The travel distance to exits on the ground floor is less than 15 m although the code permits 30 m.
ii) The fire alarm system is being extended throughout the building and other life safety systems are being provided.
iii) The building although 3 storeys in height is small in floor area (ie. 42 sq.m. on the 3rd floor).

iv) In the opinion of the Building Code Commission, the wood frame roof assembly with wired glazed skylights does not affect the performance level of the building.

Dated at Toronto this 10th day in the month of April in the year **1997** for application number **1997-06.**

RULING

1. **The Applicant**

   Mr. Galli Taberini, President, West Sutton Properties, is a person who holds a building permit under the Building Code Act, 1992 to construct an industrial building at 7345 Danbro Crescent, Mississauga, Ontario.

2. **Description of Construction**

The subject industrial building has a major occupancy of F2 and a sprinklered building area of 6,364 square metres. The exposed building face has a variety of spatial separations and unprotected openings and is constructed of wall panels which consist of a PVC shell structure fitted together and filled with concrete.

3. **Dispute**

The issue under dispute is whether the PVC wall panels which are required to be of noncombustible construction, and have a fire resistance rating of not less than 2 hours, are permitted under the spatial separation requirements of the Building Code.

4. **Provisions of the Building Code**

Sentence 3.2.3.7.(2) Construction of Exposing Building Face

2. Except as permitted in Article 3.2.3.9., where a limiting distance shown in Table 3.2.3.B. for a Group E, or Group F, Division 1 or 2 occupancy classification is such as to permit an exposing building face to have unprotected openings of
    a. not more than 10 per cent of the exposing building face, the exposing building face shall be of noncombustible construction having a fire-resistance rating of not less than 2 h and be clad with noncombustible construction,
    b. more than 10 per cent but not more than 25 per cent of the exposing building face, the exposing building face shall have a fire-resistance rating of not less than 2 h, and be clad with noncombustible cladding, and
    c. more than 25 per cent but less than 100 per cent of the exposing building face, the exposing building face shall have a fire-resistance rating of not less than 1 h.

5. **Applicant's Position**

The Applicant submitted that the building is to be considered as a 1 storey building with a 10% mezzanine and constructed of combustible construction. The Applicant submitted that Table 3.2.3.1.D of the National Building Code permits a limiting distance of 15 metres in a sprinklered, F2 building with 100% unprotected openings, which would permit the north and south walls of the building. The Applicant further submitted that the 1995 National Building Code permits these walls to have a 1 hour fire separation and combustible exterior cladding and submitted ULC tests indicating that the wall assembly meets a 2 hour fire separation. The Applicant indicated that the project should be considered as an equivalent to the requirements of the 1995

NBC, and that the same spatial separation tables are being proposed for the 1998 Ontario Building Code.

6. **Chief Building Official's Position**

The Chief Building Official submitted that because the mezzanine is designed to be in excess of 10% the building is a non-combustible 2 storey building. The Chief Building Official further submitted that the wall panel is to be constructed from noncombustible materials since the building classification and limiting distance provided requires the cladding to be constructed from noncombustible materials. The Chief Building Official also submitted that the wall panels had not been tested to meet the 2 hours fire resistance rating.

7. **Commission Ruling**

It is the decision of the Building Code Commission that the exterior wall assembly consisting of PVC shell panels, filled with concrete provides sufficiency of compliance with Sentence 3.2.3.7.(2) of the Building Code provided that the building meets the construction requirements of a 1 storey building plus mezzanine as per Article 3.2.2.52 of the Building Code.

8. **Reasons:**

ii. The Commission is of the opinion that in fully sprinklered buildings, where the sprinkler system is supervised and monitored, the sprinkler system will control fire to such an extent that there will be limited radiation through openings in the exterior face and that there is a substantial reduction in the potential for fire to spread within the building.

iii. The building is essentially of non-combustible construction where combustible construction is permitted.

iv. U.L.C. test data was provided as evidence indicating a 2 hour rating on the wall assembly with a full report to be submitted to the municipality.

v. The 1995 National Building Code permits combustible cladding and a 1 hour rated wall.

vi. Proposed changes for the 1997 Ontario Building Code would accept the proposed construction.

APPEARANCES

Mr. Fred Wood, Architect
Leonard Alfred Wood Architect
The Agent for the Applicant

RULING

1. **The Applicant**

   Mr. William Isbell, President of Golf Way Developments has applied for a building permit under the Building Code Act, 1992 to construct an air-supported structure at 141 Northern Avenue, Thunder Bay, Ontario.

2. **Description of Constrution**

   The subject building is a new 1 storey building with a building area of 8,361 square metres. The air-supported structure with a fabric roof has a mezzanine running the full length of the building. Interior partitions are made of noncombustible construction and an ancillary space which houses washrooms and the entrance lobby are separated from the areas under the roof by a 1 hour fire separation.

3. **Dispute**

   The issue in dispute is whether the building as designed with interior partitions and with an attached ancillary structure meets the requirements for air-supported structures in Subsection 3.1.6. with regards to the mezzanine area, partitions, and spatial separations to the adjacent property.

4. **Provision of the Building Code**

   3.1.6. Tents, Air-supported structures and temporary structures

   3.1.6.2. Application

3. Air-supported structures shall be designed primarily as open floor space without interior walls, mezzanines, intermediate floors or similar construction.

3.1.6.3. Clearance to Other Structures

4. Except for tents used for camping and other personal uses and except as provided in Sentences (2), (3) and (4), every tent, air-supported structure and temporary structure shall conform to Subsection 3.2.3.
5. Tents and air-supported structures shall not be erected closer than 3 m (9 ft 10 in) to other structures on the same property except as provided in Sentences (3) and (4), and shall be sufficiently distant from one another to provide an area to be used as a means of emergency egress.

5. **Applicant's Position**

The Applicant submitted that many of these air-supported structures have been constructed successfully in Ontario and Manitoba and proposes to construct the building in accordance with Article 3.2.2.23. and the proposed revisions to Subsection 3.1.6. of the Ontario Building Code.

Fire alarm system and exits are provided in parts of both the air supported structure and ancillary building.

6. **Chief Building Official's Position**

The Chief Building Official submitted that Sentence 3.1.6.2.(3) of the Building Code states that air-supported structures shall be designed primarily as an open floor space without interior walls, mezzanines, or intermediate floors. In addition, the Chief Building Official submitted that the Building Code does not allow the Chief Building Official to accept interior partitions or apply standards to those partitions or mezzanines.

7. **Commission Ruling:**

It is the decision of the Building Code Commission that the air supported structure provides sufficiency of compliance with Subsection 3.1.6. of the Building Code provided:

. The storage garage is separated from the air supported structure by a 1.5 h fire separation;
i. No additional interior walls or mezzanines be constructed, over and above those presently proposed;
ii. Existing mezzanines not be enclosed;

iii. The attached lobby building is sprinklered;

iv. The occupant load is limited to no more than 150; and

v. The travel distance from the mezzanines to an exit is no more than 30 m.

2. **Reasons:**

. The Building Code does not prohibit interior walls or mezzanines in air supported structures but requires that they be designed primarily as open spaces. The proposed structure contains limited interior walls with approximately 5% of its floor area as open mezzanines.

i. The building meets the requirements of Sections 3.3 and 3.4 of the Building Code.

RULING

1. **The Applicant**

   Mr. Mitchell Hall, Associate, Montgomery & Sisan / Kuwabara Payne McKenna Blumberg Architects in joint venture, is the holder of a permit issued under the Building Code Act, 1992 to construct a new 4 storey home for the aged at the Providence Centre, Scarborough, Ontario.

2. **Description of Constrution**

   The proposed construction is a new 4 storey home for the aged made of combustible construction and a basement and building area of 4,825 square metres. The building is fully sprinklered, with a fire alarm system and standpipe and hose system, and is connected to the existing facility by means of a tunnel. The exits from the basement is through two unenclosed exterior stairways.

Paired doors are provided across the corridors to define the zones as required by the Building Code.

3. **Dispute**

The issues in dispute are whether: 1) the requirement of Sentence 3.2.3.13.(2) to protect ground floor windows located beside the unenclosed exterior exit stairs should be applied to this situation; and 2) the swing of the paired doors dividing the corridors may be the reverse of that required by 3.3.1.10.(3) of the Building Code.

4. **Provision of the Building Code**

3.2.3.13. Protection of Exit Facilities

2. Where an unenclosed exterior exit stair or ramp may be exposed to fire from openings in the exterior walls of the building it serves, the openings in the exterior walls of the building shall be protected with wired glass in fixed steel frames or glass block conforming to Article 3.1.8.14. where the openings in the exterior walls of the building are within 3 m (9 ft 10 in) horizontally and
    a. less than 10 m (32 ft 10 in) below the exit stair or ramp, or
    b. less than 5 m (16 ft 5 in) above the exit stair or ramp.

3.3.1.10. Door Swing

3. Where the corridor in Sentence (2) is divided by paired doors which provide access to exit in opposite directions,
    a. the doors shall swing on a vertical axis,
    b. the doors shall swing in opposite directions, and
    c. the right hand door shall swing in the direction of exit travel.

5. **Applicant's Position**

The Applicant submitted that glazing exists within 3 metres of the exterior stair serving the basement but that the basement area will have a low occupant load used by staff only. The Applicant went on to state that the basement has a limited travel distance to the exterior doors, and that if the exterior stairs were enclosed in a lobby area they could have an additional travel distance of up to 15 metres.

Regarding the pair of doors across the corridor, the Applicant submitted that due to the layout of the corridor and the adjacent suites, the more practical design would be to have the left hand door swing in the direction of travel incorporating proper signage and door hardware. The Applicant further submitted that the occupants would be assisted by staff familiar with the door operation when moving occupants from one zone to another.

6. **Chief Building Official's Position**

The Chief Building Official submitted that the glazing on the ground floor is within 3 meters of the exterior exit stair serving the basement and that the Applicant does not want to provide wire glass and steel frames or an equivalent design to the very specific requirements of Sentence 3.3.3.13.(2).

Regarding the issue of the doors swinging across the corridor, the Chief Building Official submitted that the condition occurs on 2 sets of doors per each of the 4 floors for a total of 8 sets, and that the Applicant does not want to revise the design to comply with Sentences 3.3.1.10.(3) and 3.3.3.3.(3) of the Building Code which is very specific in requiring the right hand door to swing in the direction of travel.

7. **Commission Ruling:**

It is the decision of the Building Code Commission that:

ii. The swing on the corridor doors provides sufficiency of compliance with the requirements of the Building Code and;
iii. Not providing wired glass in fixed frames adjacent to the unenclosed exterior stair does not provide sufficiency of compliance with the Building Code.

2. **Reasons:**

ii. The double corridor door system with left hand swing in the direction of travel provides a similar level of performance to that of a pair of doors with the right hand door swinging in the direction of travel.
iii. The corridor doors will be suitably marked to facilitate proper operation.
iv. The doors will be equipped with push bars to facilitate operation.
v. The building is required to have a fire safety plan with designated supervisory staff to assist in the movement of occupants.
vi. Users of the unenclosed exterior stairs may be exposed to fire from the adjacent window without wired glass in fixed frames.

Dated at Toronto, this 26th day, in the month of March, in the year 1997, for application number 1997-04.

The Respondent

RULING

1. **The Applicant**

   Mr. Michael Schuster, General Manager, Rosati Walbridge, is the holder of a permit issued under the Building Code Act, 1992 to construct a gymnasium addition at the Gosfield North Public School, in Gosfield Township North, Ontario.

2. **Description of Constrution**

   The proposed construction is the addition of a gymnasium to an existing school. The addition is one storey, 1,121 square metres (12,062 ft²), unsprinklered, and of combustible construction. The underside of the roof assembly is 5.5.metres above the finished floor. The existing school is 3,406 square metres (36,650 ft²).

3. **Dispute**

The dispute between the Applicant and Respondent concerns sufficiency of compliance with Article 2.1.3.1. of the Building Code. The issue in dispute is whether a two hour fire separation can be provided in lieu of a firewall between the new addition and the existing school.

4. **Provision of the Building Code**

2.1.3.1. Building Divided by Firewalls

1. Where a firewall divides a building, each portion of the building so divided shall be considered as a separate building, except for the purpose of
    a. gross area determination in Section 2.3,
    b. a fire alarm and detection system in Sentence 3.2.4.2.(1) or Article 9.10.17.1., or
    c. a plumbing system interconnected through a firewall.

5. **Applicant's Position**

The applicant submitted that alternative measures under Part 11 be used to address deficiencies with respect to fire separations, and constructing a 2 hour fire separation between new and existing portions of a building in lieu of a firewall, provides sufficiency of compliance with the Building Code.

6. **Chief Building Official's Position**

The Respondent submitted that there is no authority to accept the use of a 2 hour fire separation in lieu of a firewall as per 2.1.3.(1). The roof extends above 6 metres from the finished floor and has insufficient fire rating, and the addition includes combustible construction.

7. **Commission Ruling:**

It is the decision of the Building Code Commission that the 2 hour fire separation provides sufficiency of compliance with Article 2.1.3.1. and 3.1.10. of the Building Code provided that:

i. The closures (doors 3 & 9) in the wall separating the new gym and the existing gym have a 1-1/2 hour fire resistance rating.
ii. That the rooms 102, 103 and 104 are provided with heat detection connected to the fire alarm system and
iii. The proposed 2 hour fire separation is provided.

8. **Reasons:**

. The new wall of the gym except for minor variances at the corridor appear to comply with fire wall construction.

i. Additional detection and compartmentation is provided.

Dated at Toronto, this 11th day, in the month of March, in the year 1997, for application number 1997-09.

For the Respondent

RULING

1. **The Applicant**

   Mr. Heinz Vogt, Partner, Stone Kohn McQuire Vogt Architects is a person who holds a permit under the Building Code Act, 1992 to renovate 11 units of an existing apartment building, at Bello Horizonte, 1500 Keele Street, City of York, Ontario.

2. **Description of Constrution**

   The subject building is a 124 unit apartment building. The proposed construction is to convert 11 existing apartment units into barrier free suites beyond normal barrier free design principles.

3. **Dispute**

   The dispute between the Applicant and the Respondent concerns whether the conversion of the 11 units is to be classified under a residential or institutional major occupancy.

4. **Provision of the Building Code**

   3.1.2.1. Classification of Buildings (excerpts)

1. Except as provided in Articles 3.1.2.3. to 3.1.2.6., every building or part thereof shall be classified according to its major occupancy as belonging to one of the Groups or Divisions described in Table 3.1.2.A.
2. A building intended for use by more than one major occupancy, shall be classified according to all major occupancies for which it is used or intended to be used.

Table 3.1.2.A.

Group	Division	Description of Major Occupancies
B	1	Institutional Occupancies in which persons are under restraint or are incapable of self preservation because of security measures not under their control
B	2	Institutional ocupancies in which persons require supervisory care, medical care or treatment
A	-	Residential Occupancies

Sentence 3.1.3.5.(1) Exceptions for Major Occupancies

3. In a building where the aggregate area of all major occupancies in a particular Group or Division is not more than 10 percent of the floor area of the storey on which they are located, these major occupancies need not be considered as major occupancies for the purposes of Subsection 3.2.2. provided they are not classified as Group F, Division 1 or 2 occupancies.

5. **Applicant's Position**

The Applicant submitted that based on the level of care provided the occupancy is residential. The Applicant submitted: a copy of the Service Agreement between the Participation Apartments and the tenants of the units in dispute; a letter to the City of York outlining how the life safety concerns of the tenants are being addressed through the availability of full time non-medical staff; that 45 minute rated doors would be provided for each unit; that an early warning alarm system to a central location for each of the 11 units would be installed; and, a fire plan which incorporates procedures agreed upon between the fire department, Participation Apartments, and Bello Horizonte would also be instituted. The Applicant further submitted that in accordance with Sentence 3.1.3.5.(1) the conversion of the 11 units represents less than 10% of the total floor area and that no significant change in building classification is justified.

6. **Chief Building Official's Position**

The Respondent submitted that the level of disability of these persons plays an important role in determining the major occupancy of the building and that the proposed type of use is not appropriate in a building having a Residential Occupancy Group C classification. The Respondent submitted that under normal circumstances, disabled persons would reside in a residential building if the building met the requirements for Barrier-Free design under Section 3.7. of the Building Code. However based on and analysis of CAN/CSA B651-95, the Respondent submitted that the level of disabilities of the intended occupants exceed the scope of normal Barrier free design principles and therefore does not belong in a Group C major occupancy. The Respondent indicated that the intended occupants will require full supervisory care which is more according to Institutional rather than Residential occupancies. The Respondent also indicated that Article 3.1.2.5. specifies that convalescent homes and children's custodial homes can be classified as a Group C occupancy where the occupants are ambulatory. Since the proposed tenants are not ambulatory, the proposed use should belong to other than a Group C major occupancy.

The Respondent confirmed that the aggregate area of the second major occupancy does not exceed 10% of the floor area of the storey in which it is located, but that this provision does not exempt the second major occupancies from dealing with the requirements of Sections 3.1., 3.2. and 3.3.

7. **Commission Ruling:**

It is the decision of the Building Code Commission that the conversion of 11 units facilities for physically disabled in an existing multi-unit apartment building is to be classified as a residential use under Section 3.12 of the building code provided that the following additional safety measures are included in the buildings,

i. The doors to the converted suites are to have a 3/4 hour fire resistance rating.
ii. Smoke alarms provided in these suites shall be connected to a listed monitoring panel located in the staff office.
iii. Doors to the affected suites shall be gasketted to minimize infiltration of smoke in the event of fire.
iv. The fire safety plan is to be modified to address the additional fire safety needs of specific residents and staff is to be assigned support responsibilities.
v. No additional units will be introduced for this use within the building.

8. **Reasons:**

. Physically disabled residents live independently within these units and direct their own care through the purchase of service.

i. Non-medical support care is provided on a 24 hour basis through a signed service agreement.

ii. Additional life safety measures are included such as compartmentalization, early warning and control of smoke movement.

iii. The residents are cognisant of their surroundings and have the ability to direct their own care.

Dated at Toronto, this 26th day, in the month of February, in the year 1997, for application number 1997-08.

RULING

1. **The Applicant**

   Mr. Lawrence Carter, Architecture Incorporated Architect, is a holder of a permit under the Building Code Act, 1992 to construct an addition to join two existing industrial buildings and add a second floor/mezzanine, at Kuntz Electroplating, Kitchener, Ontario.

2. **Description of Constrution**

   The proposed construction is an addition to join two existing one storey industrial buildings with an F3 major occupancy. Plant 1 has an overall building area of 18,112 square metres. The total area of the joined buildings would create an overall building area of 24,241 square metres. The construction also involves an additional mezzanine of 820 square metres. The proposed mezzanine which includes visual obstructions would result in a total mezzanine area of 12.6% of the combined total building area and 9.6% of the Plant 1 area and proposed addition. The

building is a mixture of combustible and non-combustible construction, with the newer areas of non-combustible construction having a sprinkler system and standpipe and hose system.

3. **Dispute**

The dispute between the Applicant and the Respondent concerns sufficiency of compliance with Sentences 3.2.1.1.(3) and 3.2.1.1.(4) of the Ontario Building Code. At issue is whether the construction is to be considered a mezzanine or second storey and therefore whether fire separations and exits are required.

4. **Provision of the Building Code**

Sentence 3.2.1.1. Exceptions to Building Height in Storeys

3. Except as provided in Sentences (4), (5) and (8), a mezzanine shall not be considered as a storey in calculating the building height provided
    a. the aggregate area of the mezzanine floor is not more than 40 per cent of the area of the room or storey in which it is located,
    b. it is used as an open floor area except as provided in Sentence 3.3.2.11.(2), and
    c. the space above the mezzanine floor has no visual obstructions more than 1070 mm (3 ft 6 in) above such floors.
4. Except as provided in Sentence (5), a mezzanine shall not be required to be considered as a storey in calculating building height and need not conform to Sentence (3) where the aggregate area of the mezzanine floor does not exceed 10 per cent of the area of
    a. the suite in which it is located, where there is more than one suite in the storey, or
    b. the storey in which it is located, in all other cases

5. **Applicant's Position**

The Applicant submitted that if Sentences 3.2.1.1.(3) and 3.2.1.1.(4) of the Building Code are not mutually exclusive, the floor area requirements of a mezzanine are not exceeded by the proposed construction. The Applicant further submitted that if the floor area percentages are exclusive and the proposed construction exceeds the 10% floor space limit by 2.5%, then factors such as: non-combustible construction; heat detectors and sprinklering in the metal polishing areas; fire alarm system; low occupant loads; fire hose cabinets; and, trained volunteer Emergency Response Team, all contribute to provide sufficiency of compliance with the technical requirements of the Building Code.

6. **Chief Building Official's Position**

The Respondent submitted that Sentences 3.2.1.1.(3) and (4) are to be considered separately from each other and that unless there is a fire wall provided between Plant 1 and Plant 3 the aggregate area of the mezzanine would be 12.5% of the total combined floor area, and the proposed mezzanine should be considered as a second storey for the purposes of calculating building height and assessing required fire separations and exiting requirements.

7. **Commission Ruling:**

It is the decision of the Building Code Commission that the addition of a mezzanine to the existing building to bring the aggregate area of unenclosed and enclosed mezzanines to 12.5% provides sufficiency of compliance with Sentences 3.2.1.1.(3) and 3.2.1.1.(4) of the Building Code, provided that Plant 1 is separated from Plant 3 by a 2 hour rated fire separation.

8. **Reasons:**

iii. The percentage of unenclosed and enclosed mezzanines in Plant 1 is approximately 10%.
iv. Fire emergency procedures with extensive communication systems, early detection and an industrial fire brigade enhance early warning and suppression capabilities.
v. Stand pipe and hose systems are provided through the complex and large portions of the building are sprinklered.
vi. The occupant loads for the mezzanines are low considering storage and automated manufacturing use.

Dated at Toronto, this 26th day, in the month of February, in the year 1997, for application number 1996-61.

The Applicant

Mr. David S. Prentice
Chief Building Official
Township of Puslinch
The Respondent

RULING

1. **The Applicant**

   Mr. Jeff Jacques, Owner, R.R. # 2 is a person who holds a permit under the Building Code Act, 1980 to make interior renovations and add a two storey addition to an existing one storey single unit dwelling at R.R. # 2, Puslinch, Ontario.

2. **Description of Constrution**

   The subject single unit house has a building area of 172 square metres (1,850 sq ft), is of combustible construction and is unsprinklered. Around the foundation a 305 mm (12 in) wide trench has been installed which exposes at least 150 mm of the foundation wall above grade.

3. **Dispute**

   The dispute between the Applicant and the Respondent concerns sufficiency of compliance with Articles 9.15.4.3. and 9.14.6.1. of the Ontario Building Code. At issue is whether the trench designed to expose at least 150 mm of the foundation wall above ground level and drain surface water so that it will not accumulate near the building or adversely affect adjacent properties, provides equal performance to the requirements of the Building Code.

4. **Provision of the Building Code**

9.15.4.3. Extension above Ground Level

Exterior foundation walls shall extend not less than 150 mm (5 7/8 in) above finished ground level.

9.14.6.1. Surface Drainage

The building shall be located and the building site be graded so that water will not accumulate at or near the building and will not accumulate at or near the building and will not adversely affect adjacent properties.

5. **Applicant's Position**

The Applicant submitted that the trench was designed based on an engineering report, and that there has not been a problem in terms of water accumulation or adversely affecting adjacent properties since it was installed in 1984.

6. **Chief Building Official's Position**

The Respondent submitted that the construction was not performed in a manner that provided an extension of exterior foundation walls not less than 150 mm above finished ground level as required by 9.15.4.3. The Respondent further submitted that the proposed remedy does not comply with 9.14.6.1. that requires the site to be graded so that water will not accumulate at or near the building, and in this case the Respondent does not have the authority to accept an equivalent.

7. **Commission Ruling:**

It is the decision of the Building Code Commission that the proposal provides sufficiency of compliance with the Building Code provided that a drawing prepared by and bearing the seal of an Architect or Professional Engineer, licensed in Ontario, is provided for the proposed compliance alternative. A letter confirming that based on a site review, that the final installation complies with the sealed drawing is also to be provided by the same Architect or Engineer.

8. **Reasons:**

It appears from information provided by the Applicant that the condition has existed since 1984 and there has been no problems with water accumulation. This may be considered as past performance under Article 9.3.0.4. of the 1983 Building Code.

RULING

1. **The Applicant**

   Mr. Graeme A. Clark, Carriage Hills Resort is the holder of a permit under the Building Code Act, 1992 to construct 2 and 3 storey multi-unit residential buildings at the Carriage Hills Resort at Horseshoe, Barrie, Ontario.

2. **Description of Constrution**

   The proposed buildings are Group C Residential Occupancy, of 2 and 3 storeys and having a building area of approximately 19,000 square feet with firewalls to create buildings of approximately 6300 square feet and therefore classified as Part 9 buildings. The buildings are of combustible construction, and without sprinklers, fire alarm system or standpipe and hose systems.

Each unit is one storey and the egress from the upper storey units is via a balcony or porch at the front of the units which is provided with a single open stair down to grade level. Each unit is provided with a balcony at the rear which does not have access to grade from the upper storeys.

3. **Dispute**

The dispute between the Applicant and the Respondent concerns whether the upper storey units provide a means of egress that complies with the intent of the Building Code.

4. **Provision of the Building Code**

9.9.9.3. Shared Egress Facilities

1. A dwelling unit shall be provided with a second and separate means of egress where an egress door from the dwelling unit opens onto: a) an exit stairway serving more than i suite, b) a public corridor serving more than 1 suite served by a single exit stairway, c) an exterior passageway serving more than one suite and served by a single exit stairway, or d) a balcony serving more than one suite and served by a single exit stairway.

5. **Applicant's Position**

The Applicant submitted that the fire separated balcony for each unit on the 2nd and 3rd floors meets the intent of the Building Code by providing an additional means of egress.

6. **Chief Building Official's Position**

The Respondent submitted that the design of the building means that a second means of egress is required under Article 9.9.9.3. of the Building Code.

7. **Commission Ruling:**

It is the decision of the Building Code Commission that the required 2nd means of egress from the dwelling units to balconies that do not lead to grade does not provide sufficiency of compliance with Article 9.9.9.3. of the Building Code.

8. **Reasons:**

i. No access to a public thoroughfare is provided from the balconies.
ii. No additional compensating measures are provided.

Dated at Toronto, this 13th day, in the month of February, in the year 1997, for application number 1996-62.

RULING

1. **The Applicant**

   Mr. Mohammed Mohebbi, Plaston Architect Ltd., is the holder of a permit under the Building Code Act, 1992 to construct at the "Volvo Villa Flagship" new car dealership at 212 Steeles Avenue West, Vaughan, Ontario.

2. **Description of Constrution**

   The subject building is a 2 storey commercial building with an F2 major occupancy of non-combustible construction and a building area of 1,892 square metres. The car dealership is proposing a showroom area in the basement and on the main floor, and a car delivery area.

3. **Dispute**

   The dispute between the Applicant and the Respondent concerns whether the ventilation requirements of a showroom and car delivery area are to be considered upon the requirements of Section 3.1.16.1. and Sentence 6.2.2.1.(3), or, are to be considered as a storage garage and comply with the ventilation requirements of Section 6.2.2.3. of the Building Code.

4. **Provision of the Building Code**

Sentence 6.2.2.1.(3) Required Ventilation

3. "Except for Group C and Group F occupancies, mechanical ventilation throughout the occupied zone shall be not less than 7.5 L/s (15.9 cfm) per person of outdoor air."

Article 6.2.2.3. Ventilation of Storage and Repair Garages

4. "...an enclosed storage garage shall have a mechanical ventilation system designed to ...(b) provide, during operating hours, a continuous supply of fresh air at a rate equal to not less than 3.9 L/s (8.3 cfm) for each square metre of floor area..."

5. **Applicant's Position**

The Applicant submitted that the mechanical ventilation for the showroom and new car delivery area should be designed based upon the area being a Group E mercantile occupancy. The Applicant further submitted that the areas have air handling units which exceed the requirements for Group E major occupancies

6. **Chief Building Official's Position**

The Respondent submitted that the automobile showrooms and new car delivery area are to be considered as storage garages and required to comply with Article 6.2.2.3. In addition, the Respondent indicated that the Building Code requires a mechanical ventilation system even when vehicles are parked by mechanical means, because of the concern that when vehicles are being parked or stored in a building there is a potential for carbon monoxide contamination within the occupied space.

7. **Commission Ruling:**

It is the decision of the Building Code Commission that the ventilation requirements for the automobile showrooms and the new car delivery areas are not subject to the requirements of Article 6.2.2.3. of the Building Code.

8. **Reasons:**

. The showrooms are not considered storage garages and are subject to 6.2.2.1.(3) of the Building Code.

i. The show rooms are intended for display of motor vehicles.

ii. The ventilation air handling systems are provided with CO detectors.

iii. A branch opinion is being prepared to clarify the definition of storage garage and storage of vehicles for display purposes.

Dated at Toronto, this 13th day, in the month of February, in the year 1997, for application number 1997-01.

The Respondent

RULING

1. **The Applicant**

   Mr. Dick Splinter, Braebury Homes Corporation is the holder of a permit under the Building Code Act, 1992 to construct a semi- detached house located on Lot 20, Highmont Court, Kanata, Ontario.

2. **Description of Constrution**

   The subject building is a 2 storey semi-detached house of combustible construction with a building area of 169 square metres (1,816 sq ft). A stair which serves as the only egress for the second floor is comprised of a combination of a straight portion, a winder, and a curved portion.

3. **Dispute**

   The dispute between the Applicant and the Respondent concerns whether the use of a straight portion, a winder, and a curved portion in combination in the same interior stair within a dwelling unit meets the requirements of Section 9.8. of the Building Code.

4. **Provision of the Building Code**

   9.8.2.1.(2) Uniform Treads and Risers

   2. A stairway that is not an exit may contain both a curved and straight portions of stairs in a single flight provided each curved portion conforms to Article 9.8.5.2. and the riser height is uniform throughout the flight.

   9.8.5.3. Winders

3. Stairs within dwelling units may contain winders that converge to a centre point provided the winders turn through an angle of not more than 900 and individual treads turn through an angle of 300.
4. Only one set of winders described in Sentence (1) shall be permitted between floor levels.

5. **Applicant's Position**

The Applicant submitted that the stairs as designed has all three accepted types of stairs - straight, winder and curved, and in every way meet the both the intent and the written Building Code. The Applicant further submitted that the Building Code now allows winders in any stairs.

6. **Chief Building Official's Position**

The Respondent submitted that Article 9.8.2.1.(2) allows a curved and straight stair but does not restrict or permit a combination of straight, curved, and winder stairs in a single flight. The Respondent further submitted that if 2 winders are not permitted as per Sentence 9.8.5.3.(2) , then the proposed layout should also not be permitted as it appears to be more hazardous than Figure 5.4.4.a. from the "Code and Construction Guide".

7. **Commission Ruling:**

It is the decision of the Building Code Commission that the proposed combination of straight, winders, and curved stairs provides sufficiency of compliance with Article 9.8.2.1. of the Ontario Building Code.

8. **Reasons:**

. A stair connecting two floor levels within a dwelling unit is not an exit but an egress facility and Sentence 9.8.2.1.(2) applies.
i. The Building Code Sentence 9.8.2.1.(2) allows a stairway that is not an exit to contain both curved and straight portions.
ii. The curved portion meets the requirements of Article 9.8.5.2. of the Building Code.
iii. The winders in the stair are in compliance with Article 9.8.5.3. of the Building Code.
iv. Section 9.8. does not prohibit the combination of curved, straight and winders in a stair under Sentence 9.8.2.1.(2).
v. The riser height is uniform throughout the flight.,/OL>

RULING

1. **The Applicant**

   Ms. L.E. Rosenberg is the holder of a permit under the Building Code Act, 1992 to construct a multi-storey parking garage, at the Oshawa General Hospital at Alexandra Street, Oshawa, Ontario.

2. **Description of Constrution**

   The subject building is a parking garage consisting of 4 storeys open and above grade and 2 storeys below grade. The building is approximately 4,716 square metres in foot print area (total of 31,000 square metres) consisting of non-combustible construction with a sprinkler system on the below grade levels. Floor drains for the four above grade storeys will be connected to a storm drain system with oil interceptors and the two below grade storeys will be connected to a sanitary drain system.

3. **Dispute**

The dispute between the Applicant and the Respondent concerns whether Sentence 7.4.4.3.(2) of the Building Code requires an oil interceptor to be provided on the sanitary sewer line that serves the two below grade floors of a parking garage.

4. **Provision of the Building Code**

7.4.4.3.(2) Interceptors

Where the discharge from a fixture may contain oil or gasoline, an oil interceptor shall be installed.

5. **Applicant's Position**

The Applicant submitted that the above grade storeys connected to a storm drainage system are equipped with oil interceptors. The below grade storeys will be drained to a sanitary drainage system that will be connected to a water treatment plant.

6. **Chief Building Official's Position**

The Respondent submitted that the Building Code does not exempt parking garages and that Sentence 7.4.4.3.(2) of the Building Code requires that an oil interceptor be installed before connecting to the sanitary drainage system.

7. **Commission Ruling:**

It is the decision of the Building Code Commission that the floor drains in the two levels below grade of the proposed parking garage, connected to the existing sanitary drain system without oil interceptors, provides sufficiency of compliance with Sentence 7.4.4.3.(2) of the Building Code.

8. **Reasons:**
    1. The risk of discharge of oil or gasoline is deemed to be minimal in a parking garage based on the recommendations of the Interceptor Task Force to the Ministry of Municipal Affairs and Housing 1997 Ontario Building Code Proposals: "The consensus of the group is that parking garages not be required to have an oil interceptor".
    2. An oil interceptor is being provided for the floor drains from the upper four floors, connected to the storm drain system.

3. The waste through the sanitary drain system is treated at a waste treatment plant prior to discharge.

Mr. David McGee
1103118 Ontario Limited
For the Respondent

REPORT

1. **Order of Ontario Court (General Division)**

   Mr. David McGee (the "Respondent") was issued an order to comply under the Building Code Act, 1992 and applied to the Ontario Court (General Division) under s.25(1) of the Building Code Act, 1992 for a declaration that Section 9.5. of the Building Code does not apply to existing a house at 74 Maitland Street, London, Ontario. In that application, the Honourable Justice Gordon Killeen of the Ontario Court (General Division), on July 4, 1995 referred for a hearing and report on the following 3 questions:

   i. "...the question raised by Mr. McGee about compliance with heating requirements..."
   ii. whether "s. 9.5. of the Building Code apply to the house owned by 1103118 at 74 Maitland Street..."; and,
   iii. "...if s. 9.5. does apply, then has 1103118 complied with its requirements such that a building permit should issue permitting the conversion of 74 Maitland Street to a duplex."

2. **Background**

   The City of London issued an order to comply on March 8, 1995 to Mr. David McGee for undertaking renovations of a house at 74 Maitland Street because the work meant that two

bedrooms would have a lack of adequate heating facilities. The City also refused to issue a building permit for the conversion of the house into two separate units because the floor area requirements of Section 9.5. were not met.

Mr. McGee appealed these actions under s. 25(1)-(2) of the Building Code Act to the Ontario Court (General Division). On July 4, 1995 Justice Gordon Killeen referred certain questions respecting the interpretation of the technical requirements of the Building Code or the sufficiency of compliance with the technical requirements of the Building Code.

As the Applicant in the proceedings before Justice Gordon Killeen had not yet applied to the Building Code Commission, the Chief Building Official applied to the Commission on October 14, 1995.

3. **Description of Construction**

The building which has been renovated is a one storey house which has been converted into a bachelor unit of 17.8 square metres at the front and a two bedroom unit at the back. The 2 two bedrooms in the rear unit have areas of 5.8 square metres and 6.1 square metres.

The original house was heated by a gas space heater, which has been replaced with a new gas fireplace and supplemented with baseboard heaters.

4. **Issue on Reference**

The reference from the Ontario Court (General Division) directed that the Building Code Commission interpret the technical requirements of the Building Code or the sufficiency of compliance with the technical requirements of the Building Code that were raised in the application before the Ontario Court (General Division) pursuant to which the reference was ordered, and in particular to determine:

i. Have the heating requirements of s. 9.33.1.3.(1) been met?
ii. "Does s. 9.5. of the Building Code apply to the house owned by 1103118 at 74 Maitland Street ?
iii. If s. 9.5. does apply, then has 1103118 complied with its requirements such that a building permit should [be] issue[d] permitting the conversion of 74 Maitland Street to a duplex ?" and

5. **Provision of the Building Code**

Clause 11.3.4.1.(1)(b) Reduction in Performance Level

The performance level of a building is reduced where proposed construction will result in...b) the conversion of a suite of a Group C major occupancy into more than one suite of a Group C major occupancy.

Sentence 11.3.4.1.(7)

Where proposed construction will result in a change of major occupancy described in Clauses 1 (a) to (d), additional construction shall be required in order that the building or part of the building subject to the change in major occupancy conforms to the requirements of...Sections 3.6, 3..11, 9.5 and 9.7...as they apply to the new major occupancy that the building or part of the building is to support.

Section 9.5. Compliance Alternative C88

Table 11.2.3.C

C88: "Except as provided in C88.1, the requirements under this Section do not apply"

C88.1: "In detached houses, semi-detached houses, townhouses and row houses containing not more than two dwelling units,

a. minimum room height shall not be less than 1.95 m (6 ft 5 in) over the required floor area and in any location that would normally be used as a means of egress, or
b. minimum room height shall not be less than 2.03 m (6 ft 8 in) over at least 50% of the required floor area, provided that any part of the floor having a clear height of less than 1.4 m (4 ft 7 in) shall not be considered in computing the required floor area.

6. **Applicant's Position**

The Applicant submitted that by virtue of Number C88.1 of Table 11.2.3C, the floor area requirements of Section 9.5. are applicable to renovations under Part 11.

The Applicant further submitted that the two bedrooms off the living room and the bathroom at the rear were not equipped with heating facilities capable of maintaining an indoor air temperature of 220 C, that there is no evidence of any ductwork or central heating in the rooms, and that the gas fireplace serves only the room or space in which it is located and not other rooms.

7. **Respondent's Position**

The Respondent submitted that the bedrooms in the rear unit were existing bedrooms that should not have to be altered to conform to Part 9 of the Building Code.

The Respondent further submitted that the house was originally heated with a gas space heater and that a new gas fireplace with some baseboard heaters should be more than adequate an improvement, and submitted 2 affidavits from tenants that the rooms were being maintained at a temperature above 220 C.

The Respondent further submitted an affidavit from a professional architect concurring with the applicant's position that the room dimensions and heating requirements meet the Building Code.

8. **Findings and Conclusions**

It is the decision of the Building Code Commission that:

. Section 9.5. of the Building Code does not apply to the renovation of the house owned by 1103118 at 74 Maitland Street.

i. The question of heating system compliance is no longer applicable.

9. **Reasons:**

. Article 11.3.4.1. of the Building Code requires conformance to Section 9.5., however Sentence 11.2.3.1.(2) indicates that a compliance alternative to a requirement in Part 9 may be substituted. Compliance Alternative C88 indicates that the requirements of Section 9.5. do not apply except for the requirements of Article 9.5.2.1. which deal only with minimum ceiling heights as detailed in compliance alternative C88.1.

i. Since the court's referral to the Commission the Respondent has installed baseboard heaters. Accordingly the parties have agreed that the Commission need not deal with this issue.

Dated at Toronto, this 8th day, in the month of January, in the year 1997, for application number 1996-69.

BCC Ruling No. 96-54-537

BUILDING CODE COMMISSION DECISION ON B.C.C. #96-54-537

IN THE MATTER OF Subsection 24(1) of the *Building Code Act, 1992.*

RULING

1. **The Applicant**

   Mr. Herbert M. Green, Chairman, River Oaks Homes Inc. is a person to whom an order to Comply was issued under the Building Code Act, 1992 to construct a single unit house as part of the River Oaks subdivision, Oakville, Ontario.

2. **Description of Constrution**

The subject building is a single unit house 2 stories high with a living area of 208 square metres (2,235 square feet). A spiral stair serves a second floor loft office which has an area of less than 20 square metres. The proposed spiral stair has rise and run dimensions that do not comply with Article 9.8.5.2. The building contains a primary staircase that complies with the Building Code requirements.

3. **Dispute**

The dispute between the Applicant and the Respondent concerns sufficiency of compliance with Sentence 9.8.3.1.(1) and Article 9.8.5.2. of the Ontario Building Code. At issue is whether the rise and run of the spiral stairs provide sufficiency of compliance with the Building Code.

4. **Provision of the Building Code**

Sentence 9.8.3.1.(1) Rise and Run of Stairs

1. Except for stairs to areas used only as service rooms, interior stairs within dwelling units and exterior stairs serving dwelling units shall have a maximum rise of 200 mm (7- 7/8 in), a minimum run of 210 mm (8-1/4 in) and a minimum tread width of 235 mm (9-1/4 in).

Sentence 9.8.5.2. Curved Stairs not in Exits

Except as permitted in Article 9.8.5.3., a curved stair not required as an exit shall have an average run of not less than 200 mm (7 7/8 in) and a minimum run of 150 mm (5 7/8 in) and shall have risers conforming to Article 9.8.3.1.

5. **Applicant's Position**

The Applicant submitted that the Building Code does not adequately address the installation of spiral stairs in either a primary or secondary application and that the stairs as installed are unable to meet the sections specified. The Applicant further submitted that the stairs do not pose a life safety risk, that the egress requirements are for the second floor are met by the primary stairs, that the rise of the stairs are necessary to accommodate tread width and headroom, that the spiral stairs have been successfully used in many applications, that other building standards specifically allow spiral stairs even in exits, and that the stairs are largely an architectural feature.

6. **Chief Building Official's Position**

The Respondent submitted that the stair does not comply with the Building Code and would be unsafe.

7. **Commission Ruling:**

   It is the decision of the Building Code Commission that the proposed stair provides sufficiency of compliance with Article 9.8.5.2. of the Building Code provided a gate with a latching device, swinging away from the stair is installed at the top of the landing.

8. **Reasons:**
   a. An October 1977 Building Code Newsletter published by the Ministry of Consumer and Commercial Relations reports an earlier Building Code Commission decision allowing a spiral staircase as a second stair in a dwelling where the main stair complies with the Code. The OBC had similar provisions at that time.
   b. Proposed amendments to the Building Code regarding live/work units exempts stairs to mezzanines not more than 20 square metres in area from the rise and run dimensional requirements.
   c. Evidence was provided that spiral stairs are allowed as the only means of egress in several U.S. Codes.

Dated at Toronto, this 12th day, in the month of December, in the year 1996, for application number 1996-65.

RULING

1. **The Applicant**

   Mr. Peter Nobre, Director of Leasing, First London East Developments Inc., is a person who holds a permit under the Building Code Act, 1992 to renovate a former office space to create a fitness club at the Argyle Mall at 1925 Dundas Street East in London, Ontario.

2. **Description of Constrution**

The subject building is a two storey fully sprinklered shopping centre with a building area footprint of 26,950 square metres. The second storey is 1,395 square metres which is made up of 1,210 square metres of leasable space and 185 square metres for building services. The former use of the second storey was office space and the new use is a fitness club. The existing floor assembly between the fitness club and the existing retail shops on the first floor is concrete filled metal deck supported by structural steel. An unrated lay-in ceiling tile is suspended from this deck. The building does not currently have a fire alarm and detection system.

3. **Dispute**

The dispute between the Applicant and the Respondent concerns sufficiency of compliance with Sentence 11.3.4.1.(4) of the Ontario Building Code. At issue is whether a rated fire separation is required between the major occupancy of the mall and the fitness club on the second floor.

4. **Provision of the Building Code**

Sentence 11.3.4.1.(4) Reduction in Performance Level

4. Except as provided in Sentence (5), where a major occupancy of all or part of an existing building is changed to another major occupancy and the hazard index of the new major occupancy is greater than the construction index of the existing building, upgrading of early warning and evacuation systems and additional upgrading shall be required in conformance with Part 11 of the Building Code so that the construction index of the building is increased to at least equal the hazard index of the new major occupancy that the building is to support.

5. **Applicant's Position**

The Application submitted that the work should qualify as a basic renovation because there is no change in major occupancy. The occupancy will not be an increase in hazard or occupant load. At the same time, the renovation will involve a improvement of the exit facilities, the building is fully sprinklered and the work is common industry practise. A Code complying fire alarm system will be installed for the whole building, and the applicant is willing to install smoke detectors on the retail stores under the fitness club as leases are renewed.

6. **Chief Building Official's Position**

The Respondent submitted that under the proposed renovations to the buildings, it was discovered that no fire separation existed, and that the municipality has included all fitness clubs under A2 occupancies. The Respondent further submitted that the sprinklers should not be used to waive the need for fire separations and that at least a 1 hour fire separation should be applied to between the major occupancies.

7. **Commission Ruling:**

It is the decision of the Building Code Commission that the change of occupancy provides sufficiency of compliance with Sentence 11.3.4.1.(4) of the Building Code provided:

iv. a fire alarm system that complies with the Building Code is installed.
v. additional fire detection is provided in the eight retail stores below the fitness club and,
vi. a fire separation providing a 1 hour fire resistance rating is installed between the first and second floors within 5 years.

2. **Reasons:**

iv. the provision of the fire alarm system substantially improves the performance level of the building.
v. additional detection allows for early warning and evacuation in the event of a fire
vi. the applicant agreed to provide a rated fire separation at the ceiling of the main floor to be completed within 5 years. The rated separation enhances life safety and property protection of the fitness club occupancy.
vii. There is no increase in fire load and no increase in occupant load due to the change of occupancy.

Dated at Toronto, this 8th day, in the month of January, in the year 1997, for application number 1996-59.

RULING

1. **The Applicant**

   Mr. Pat Carrozzi, Project Manager, Ontario Realty Corporation is the holder of a permit under the Building Code Act, 1992 to renovate a school to create a residential dormitory of 30 rooms, at the Centre Jules-Leger at 281 Lanark Avenue, Ottawa, Ontario.

2. **Description of Constrution**

   The subject building is a teaching centre with a building area of 8,405 square metres. The area under dispute is the renovation of a 2 storey former library wing with an area of 754 square

metres which is being renovated into a dormitory of 30 rooms to accommodate approximately 53 students.

3. **Dispute**

The dispute between the Applicant and the Respondent concerns sufficiency of compliance with Sentence 6.2.3.11.(2) of the Ontario Building Code. At issue is whether the recirculation of return air from the students' bedrooms to the mechanical room where it is mixed with fresh air from the exterior, then brought back into the furnace and recirculated back to the bedrooms provides sufficiency of compliance with the Building Code.

4. **Provision of the Building Code**

Sentence 6.2.3.11. Interconnection of Systems

2. In a residential occupancy, air from one suite shall not be circulated to any other suite nor to a public corridor or public stairway.

5. **Applicant's Position**

The Applicant submitted that the intent of the Building Code is to prevent the spread of smoke and odours between separate, self contained dwelling units of separate tenancies and that the proposed renovation is to create dormitory rooms used solely for sleeping and studying. The use of the rooms are not for self- contained suites as there are shared kitchenette and washroom facilities. The Applicant further submitted that the air handling systems will shut down immediately on the initiation of the fire alarm system and that each room is provided with a heat detector connected to the fire alarm system.

6. **Chief Building Official's Position**

The Respondent submitted that the intent of the Building Code is to prevent contamination of residential suites from smoke and odours generated in adjacent suites and also to protect the integrity of the public exit corridor so that the occupants have a reasonable time to exit the building. The Respondent further submitted that Sentence 6.2.3.11.(3) is applicable to all occupancies. including residential occupancies.

7. **Commission Ruling:**

It is the decision of the Building Code Commission that the design of the HVAC system provides sufficiency of compliance with Sentence 6.2.3.11.(2) of the Building Code.

8. **Reasons:**

    b. The operation of the facility is under a single tenancy and individual sleeping rooms are not considered as suites.
    c. 24 hour supervision will be provided by at least 2 staff members.
    d. Duct type smoke detectors are provided in the return air ducts.
    e. Additional compartmentalization of the floor area between sleeping rooms and corridors, provide an increased level of protection.

RULING

1. **The Applicant**

   Mr. Art Welter, Development Manager, for Devan Properties Ltd. is the holder of a permit under the Building Code Act, 1992 to provide a two stage fire alarm system in a shopping mall known as the "Cambridge Centre" located at 355 Hespeler Road, Cambridge, Ontario.

2. **Description of Constrution**

The subject building is a shopping mall of non-combustible construction with a gross floor area of 46,451 square metres (500,00 sq.ft.) consisting of 2 "anchor" tenants and a mall. The mall has a fire alarm system and the two anchor tenants have separate fire alarm systems all interconnected to act as a single system. The two stage system is intended to operate such that alarm signals activated in anchor tenants or the mall only operate in the portion of the building in which the alarm was originated and thereafter in the rest of the complex within 5 minutes if not acknowledged or an alarm initiating device is activated.

3. **Dispute**

The dispute is whether the sequence of operation of the fire alarm system, which is as follows, complies with the Building Code:

- alert signals in the mall or any anchor store will indicate a trouble signal in other panels;
- alarm signals in the mall or any anchor store will initiate alert signals in other areas;
- the mall or the anchor stores will go to alarm signals if alert signals are not acknowledged within 5 minutes or when a second stage device is activated.

4. **Provision of the Building Code**

Sentence 3.2.4.4.(2) Description of Fire Alarm Systems

2. A 2 stage fire alarm system shall
    a. cause an alert signal to sound upon the operation of any manual pull station or fire detector,
    b. except for Group B, Division 2 major occupancies, automatically cause an alarm signal to sound if the alert signal is not acknowledged within 5 min of its initiation,
    c. have each manual pull station equipped so that the use of a key or other similar device causes an alarm signal to sound and continue to sound upon the removal of the key or similar device from the manual pull station, and

2. **Applicant's Position**

The Applicant submitted that based on the past performance of this type of two stage fire alarm system in numerous existing facilities, the system provides sufficiency of compliance with subsection 3.2.4. of the Building Code. The Applicant further submitted that the alarm system enables the fire department to know where the fire originated, provides back-up in the case of major emergencies that may disable one panel.

3. **Chief Building Official's Position**

The Respondent submitted that: the operation of the alert signal will sound in one component of the building only, not throughout the total building; after the first 5 minutes the alarm signal will be sounded in that component only; once this happens an alert signal will be sent to the remaining parts of the building; and, after a further 5 minutes the alarm signal will sound in the total building. In total this system would initiate a total evacuation after 10 minutes in the total building unless the alarm signal is manually activated. Sentence 3.2.4.19.(1) states that when the alarm signal is sounded it shall be heard throughout the total floor area in which it is installed.

4. **Commission Ruling:**

It is the decision of the Building Code Commission that the two stage fire alarm system provides sufficiency of compliance with subsection 3.2.4. of the Building Code.

5. **Reasons:**

ii. The building Fire alarm system is consistent with industry practice for buildings of this type and size.
iii. The definition of alarm or alert signal is not limited to activation throughout the building.
iv. The activation of the alert signal in a specific zone will cause a trouble signal in the adjacent zones.
v. The building fire alarm system is monitored by a central monitoring station.

For the Respondent

RULING

1. **The Applicant**

   Mr. Greg Nevison, Vice President, OMNI South Inc. is the holder of a permit under the Building Code Act, 1992 to construct a multiple unit apartment building at 115 OMNI Drive, in Scarborough, Ontario.

2. **Description of Constrution**

   The subject building is a 26 storey residential building of non- combustible construction and building area of 1,020 square metres. The building is provided with a fire alarm and detection

system, a voice communication system, an automatic sprinkler system, and a standpipe and hose system.

3. **Dispute**

The dispute between the Applicant and the Respondent concerns sufficiency of compliance with Sentence 3.2.4.19.(1) of the Ontario Building Code. At issue is whether the fire alarm system provides high enough audibility levels in all areas of the building suites to be heard intelligibly.

4. **Provision of the Building Code**

Sentence 3.2.4.19.(1) Audibility of Alarm signals

1. Audible signal appliances forming part of a required fire alarm system shall be installed in a building so that alert signals, alarm signals and voice messages can be heard intelligibly throughout the floor area in which they are installed.

5. **Applicant's Position**

The Applicant submitted that the approved electrical drawings indicated that the fire alarm devices shall be sufficiently loud to be heard above normal noise levels in the area being served, and that the alarm complies with 3.2.4. of the Building Code. The Applicant pointed out that there are no numerical values of sound pressure levels in the Building Code to define acceptable audibility levels. Audible signalling appliances are installed in corridors and in all residential suites.

6. **Chief Building Official's Position**

The Respondent submitted that Sentence 3.2.4.19.(1) requires that the fire alarm system be intelligibly heard in all areas. Audibility limits must be based on good engineering practice, to perform the intended function of a fire alarm system; and that Sentence 3.2.4.19. of the 1995 National Building Code, opinion of the Office of the Fire Marshall and Section 6.3. of the N.F.P.A. 72-1993 recommend minimum sound levels of 75dBA, 65dBA and 70dBA respectively. The Respondent recommended that a dBA of 65 or 15dBA above ambient whichever is the greater be the criteria for audibility. The fire alarm system does not satisfy this requirement in some portions of the building.

7. **Commission Ruling:**

It is the decision of the Building Code Commission that the audibility of the fire alarm system provides sufficiency of compliance with 3.2.4.19.(1) provided that a professional engineer licensed in Ontario certifies under seal to the Building Department that alarm signals and voice messages can be heard intelligibly throughout the floor area in which they are installed.

8. **Reasons:**
    1. The Building Code and the referenced documents do not provide criteria for sound pressure levels.
    2. Each residential suite and public corridors are provided with audible signal appliances.
    3. The proposals for audibility criteria are presently being circulated for public comment by the Housing Development and Buildings Branch.

Dated at Toronto, this 21st day, in the month of November, in the year 1996, for application number 1996-53.

RULING

1. **The Applicant**

   Mr. Michael Cowie, Principal, Self Stor Inc. is a person who has applied for a building permit under the Building Code Act, 1992 to provide a self storage facility at 150 Bermondsey Road in North York, Ontario.

2. **Description of Constrution**

   The subject building is a greater than 5 year old 2 storey industrial building which is proposed to be renovated into a self storage facility. The building area is 3840 square metres, faces 3 streets and is a mix of combustible and non-combustible construction. Travel distance to exits is 35 metres. The individual storage spaces are constructed of steel panels and doors which are 3.06 metres high and are covered by wire mesh. The ceiling is 4 metres high.

3. **Dispute**

   The dispute between the Applicant and the Respondent concerns sufficiency of compliance with Sentence 3.10.2.4.(2) of the Ontario Building Code. At issue is whether the proposed public corridor provides sufficiency of compliance with the Building Code.

4. **Provision of the Building Code**

Sentence 3.10.2.4.(2) Safety Requirements within floor areas

2. A corridor need not be constructed as a public corridor where the travel distance, measured from inside the rental space to the nearest exit, is not more than 15 m (49 ft 3 in) provided that the corridor walls
    a. are of noncombustible construction,
    b. have no openings other than doors and the doors are of solid construction, and
    c. are continuous from the floor to the underside of the floor above, the ceiling or the roof.

5. **Applicant's Position**

The Applicant submitted that the proposed construction provides sufficiency of compliance with the Building Code by:

- being made largely of non-combustible construction;
- facing 3 streets;
- having sheet steel walls and doors both on the front and between storage lockers;
- the installation of a sprinkler system, smoke detectors and a monitored fire alarm system;
- having fire safety plans in place which include limitations on the substances being stored in the building.

The Applicant further submitted that when compared to other major occupancies (eg. F2) the proposed construction would meet the requirements of the Building Code.

2. **Chief Building Official's Position**

The Respondent submitted that a separated corridor provides benefits such as:

- smoke containment;
- the minimisation of fire spread; and,
- assistance in fire fighting because of the increased ability to locate the origin of a fire.

The Respondent further submitted the potential difficulty exists in controlling the substances being stored in the building.

3. **Commission Ruling:**

It is the decision of the Building Code Commission that the building provided sufficiency of compliance with Sentence 3.10.2.4.(2) of the Building Code provided that

. Smoke detectors are provided in the public corridor spaces connected to the fire alarm system

i. The Fire alarm system is connected to a central monitoring station and

ii. The building is compartmentalized by a minimum of 3 additional zones of approximate equal size by fire separations complete with closures with self closing devices

2. **Reasons:**

. The majority of the building is of non-combustible construction.

i. 24 gauge sheet steel walls 3.06 metres (10 ft.) in height are provided between each storage unit.

ii. Additional smoke detection is provided in the public corridor system connected to the fire alarm system.

iii. The fire alarm system is monitored by a central monitoring station.

iv. Additional containment through compartmentalization will be provided.

v. Evidence provided indicated a low occupant load.

vi. Sources of ignition are limited. No electrical power is provided directly to each unit and a no smoking policy is in place.

vii. Storage of hazardous materials (i.e. flammable liquid) is restricted by lease agreement.

viii. The fire safety plan is to be posted at each unit.

ix. The building is supervised by staff and monitored by a security system.

x. The storage height is limited by wire mesh ceiling not to impede sprinkler operation.

Dated at Toronto, this 21st day, in the month of November, in the year 1996, for application number 1996-55.

The Applicant

RULING

1. **The Applicant**

   Mr. Virgil Marques, President, V. Marques Construction Limited is the holder of a permit under the Building Code Act, 1992 for construction at a one storey house at 798 Marsh Crescent, Kingston, Ontario.

2. **Description of Constrution**

   The subject building has a kitchen floor which has been built with ceramic tile over 9.52mm (3/8 in) plywood, screwed on 15.9mm (5/8 in) plywood, and glued on the 38mm x 235mm (2 in x 10 in) joists at 400mm (16 in) o.c..

3. **Dispute**

   The dispute between the Applicant and the Respondent concerns sufficiency of compliance with Article 9.30.6.3. of the Ontario Building Code. At issue is whether the use of adhesive at the junction of the 15.9mm (5/8 in) plywood and floor joists, the screwing of the 2 layers of plywood, and the 2 rows of bridging will stiffen the assembly and provide a level of performance equal to the requirements of the Building Code.

4. **Provision of the Building Code**

Article 9.30.6.3. Reinforcement for Panel-Type Wood Sheathing

1. When ceramic floor tiles are set on panel-type wood sheathing, one of the following assemblies for reinforcing the floor assembly shall be used
    a. 20 mm (13/16in) thick plywood or waferboard with all edges supported by at least 38 mm by 38 mm (2 in by 2 in) blocking with floor joists spaced not more than 400 mm (16 in) o.c., with 6 mm (1/4 in) underlay,
    b. sheathing thickness which conforms to Table 9.23.14.A. and having an underlay consisting of 15.9 mm (5/8 in) plywood or waferboard with offsetting joints. A 4 mm (5/32 in) gap shall be provided between sheets, or
    c. sub-floor sheathing reinforced with close spaced 38 mm by 38 mm (2 in by 2 in) blocking at spacings at least half that of the floor joist spacing.

5. **Applicant's Position**

The Applicant submitted that the past performance of installing ceramic tile in this manner (glue on every floor joist and screws every 89mm) provides a level of performance that would be achieved by conforming with the requirements of the Building Code.

6. **Chief Building Official's Position**

The Respondent submitted the top layer should have been the 15.9mm (5/8 in) plywood.

7. **Commission Ruling:**

It is the decision of the Building Code Commission that the kitchen floor beneath ceramic tile provides sufficiency of compliance with the requirements of Article 9.30.6.3. of the Building Code provided 38 mm by 38 mm blocking is installed, at spacings at least half that of the floor joist spacing, under no less than 70% of the kitchen floor area.

8. **Reasons:**
    i. Closely spaced blocking installed beneath the floor and subfloor gluing to the floor joists enhance the stiffness of the floor system.
    ii. The subfloor is a tongue and groove variety providing significant edge support.
    iii. Subfloor and underlay have been screwed together in a 150mm x 150mm fastening pattern improving the load sharing characteristics of the floor system.
    iv. Evidence was provided that a written warranty could be made available to the homeowner from the ceramic tile installer.

v. The applicant stated that this method of ceramic tile floor construction has demonstrated acceptable past performance.

Bracebridge, Ontario
The Applicant

RULING

1. **The Applicant**

   Mr. Alex & Mrs. Linda Brooks, Owners, are a holder of a permit under the Building Code Act, 1992 to renovate a building at 3 South Muskoka Drive, Bracebridge, Ontario.

2. **Description of Constrution**

   The subject building is a 2 1/2 storey house of approximately 130 square metres. Spiral stairs located at the top of the stairs to the second floor allow access to a loft in the attic.

3. **Dispute**

   The dispute between the Applicant and the Respondent concerns sufficiency of compliance with the Building Code. The spiral stairs which lead from the second floor to the loft have a tread 610 mm wide, a rise of 210 mm, and an average run of 152 mm (0 mm to 305 mm).

4. **Provision of the Building Code**

   Article 9.8.3.1. Rise and Run of Stairs

   1. "...stairs serving dwelling units shall have a maximum rise of 200 mm (7 7/8 in), a minimum run of 210 mm (8 1/4 in) and a minimum tread width of 235 mm (9 1/4 in).

   "

   Article 9.8.5.2. Curved Stairs not in Exits

"Except as permitted in Article 9.8.5.3., a curved stair not required as an exit shall have an average run of not less than 200 mm (7 7/8 in) and a minimum run of 150 mm (5 7/8 in) and shall have risers conforming to Article 9.8.3.1."

5. **Applicant's Position**

The Applicant submitted that: the intent of Article 9.8.3.1. of the Building Code was to provide minimum standards for bedroom and other living space, and that the loft area will be a limited use study area; that the structural changes required to meet the Building Code would be cost prohibitive and unattractive; and, that the other Building Code deficiencies in the building are being met.

6. **Chief Building Official's Position**

The Respondent submitted that the spiral staircase is within the dwelling unit and does not meet the requirements for stairs in Article 9.8.3.1. or 9.8.5.2.

7. **Commission Ruling:**

It is the decision of the Building Code Commission that the existing circular stair to the attic loft provides sufficiency of compliance with Article 9.8.3.1. of the Building Code.

8. **Reasons:**

The Building has existed since 1988, and compliance alternative C.97 indicates that existing curved or spiral stairs are acceptable.

RULING

1. **The Applicant**

   Mr. Nick Dimitrakakis, President, 1142907 Ontario Ltd. is a person who has applied for a building permit under the Building Code Act, 1992 to increase the ground floor seating provided in a restaurant at 1402 Queen Street, Toronto, Ontario.

2. **Description of Constrution**

   The subject building is 3 stories high with a ground floor of 370 square metres currently used as a restaurant with a maximum occupant load of 30. The second and third floors are each 129 square metres and contain a total of 7 apartment units. The partial basement contains a hot water boiler. The building is of mixed combustible and non-combustible construction and is not

sprinklered. The floor and roof assemblies are generally lath and plaster on the underside of wood joists. The ceiling between the first and second floor consists of lath and plaster with a suspended ceiling of painted gypsum board and lay-in tile. The ceiling in the basement is a combination of exposed wood floor joists in some areas and damaged gypsum board.

3. **Dispute**

The dispute between the Applicant and the Respondent concerns sufficiency of compliance with Sentence 11.3.4.1.(4) of the Ontario Building Code. At issue is whether providing sprinkler protection for the basement and ground floor and not upgrading the second floor/ceiling assembly for the proposed increase in ground floor seating from 30 to 49 provides an equivalent level of performance to that intended by the Building Code.

4. **Provision of the Building Code**

Sentence 11.3.4.1.(4) Reduction in Performance Level

4. Except as provided in Sentence (5), where a major occupancy of all or part of an existing building is changed to another major occupancy and the hazard index of the new major occupancy is greater than the construction index of the existing building, upgrading of early warning and evacuation systems and additional upgrading shall be required in conformance with Tables 11.3.1.A., 11.3.1.B., 11.3.1.C. and 11.4.2.A. so that the construction index of the building is increased to at least equal the hazard index of the new major occupancy that the building is to support.

5. **Applicant's Position**

The Applicant submitted the following rationale as to why increasing the occupancy load from 30 to 49 does not warrant sprinklers in the basement and ground floor and further upgrading of the of the second floor rating:

The floor between the basement and ground level will be upgraded to provide a 1 hour fire separation.

There are three exterior exit doors at ground level from the ground floor. Two of the exits have less than 15 metre travel distance and lead directly from the seating area in the restaurant to the street.

The partial basement and ground floor do not share exit facilities.

The subject building is closer in size to buildings which have a hazard index of 3 or 4 rather than 6. The building index will be 4 once the proposed work is completed.

The fire separation between the restaurant and the residential use is for the benefit of the residential use and according to 9.5.2.6.(3) of the Ontario Fire Code, an existing membrane of lath and plaster is deemed to meet the required 1 hour fire separation. Fire rated tiles with hold down clips will be installed in place of the suspended ceiling in the restaurant. A 2 hour fire rated ceiling could be provided between the restaurant and residential occupancies.

The building has been upgraded for compliance with the residential retrofit requirements of section 9.5 of the Fire Code. The building has a recently installed fire alarm and detection system and emergency lighting.

The building faces three fire department access routes as opposed to the minimum one required by the Building Code.

A sign indicating maximum occupant load of 49 will be posted in a conspicuous location.

6. **Chief Building Official's Position**

The Respondent submitted that under the proposal, the building is to be classified as a group A-2 major occupancy. The proposed major occupancy has an assessed hazard index of 6, and the existing building has a construction index of 5 at best, but is more likely to be 4 or 3. To equal the hazard index the building is required to be upgraded by:

- providing a 1 hour fire resistance rating for the first and second floor assemblies, and;
- providing a sprinkler system in the basement and on the first floors.

The Respondent acknowledges that there is a large gap between the two major occupancies. The city has many properties that fall within this gap and expect to make proposals to the Ministry on the 1997 Building Code Amendments regarding sprinklers.

2. **Commission Ruling:**

It is the decision of the Building Code Commission that the Building provides sufficiency of compliance with Sentence 11.3.4.1.(4) of the Building Code for the proposed increase in seating from 30 to 49 in the ground floor restaurant provided that

iv. The fire separation between the basement and first floor has a 1 hour rating and the fire separation between the first and second floor has a 2 hour rating and

v. The solid core wood door between the kitchen and restaurant is equipped with a listed self closing device.

2. **Reasons:**

iv. Fire Department access is provided on 3 sides.

v. Two exits are provided from the dining hall with travel distance of 15m in lieu of 30m required by the Building Code.

vi. The supervised fire alarm system provided exceeds the Building Code requirements as additional thermal detection is provided at the dinning hall.

vii. The subject building is closer in size to buildings which have a hazard index of 3 or 4.

viii. The partial basement and ground floor do not share exits with the 2nd and 3rd floors above.

ix. The degree of compartmentation has been increased within the building.

Dated at Toronto, this 13th day, in the month of November, in the year 1996, for application number 1996-50.

RULING

1. **The Applicant**

   Mr. H.G. Oliver, Manager, Utilities & Projects, Regional Municipality of Durham is the holder of a permit under the Building Code Act, 1992 to construct a water processing facility and subsidiary administrative offices at 75 Lake Driveway East, Ajax, Ontario.

2. **Description of Constrution**

The subject building is a new 163 ML/d water supply plant. The facility can be divided into two areas, the process area and the administration area. The process area of the plant has a 7,097 m² building area and 10,249 m² floor area. The administration portion of the plant is 788 m² in building area and 1,665 m² in floor area.

Innovative landscaping and building design driven by the Environmental Assessment process resulted in:

- The entire roof and walls of the west end of the plant, of what would have normally been the superstructure, being bermed and buried. The design invites the public to walk on top and participate in leisurely activity in the area of the plant.
- Further adding to the uniqueness of the building is the fact that as one moves progressively towards the easterly part of the plant, the plant superstructure progressively becomes more exposed. Windows have been designed on a portion of the exposed superstructure to allow the public a view into the water plant.
- The entire eastern wall of the plant is exposed.
- The administration building is totally exposed.

The building is provided with a standpipe and hose system, and a fire alarm and detection system. The smoke detectors that are provided are in excess of the Building Code. Sprinkler protection is provided in selected areas of the process area of the plant and in the administration building. A central supervised fire alarm panel is provided.

The following applies to the process area of the plant:

- Occupancy
  - Typically unmanned
  - The occasional guided public tour may be held
- Construction
  - Totally noncombustible concrete wall and roof construction throughout
  - Open tanks are full of water
  - Pipes carry water or noncombustible water treatment chemicals
  - The only combustible load is the insulation on the electrical wiring
  - The risk of fire is extremely low

The Administration area of the plant can be best described as follows:

- Occupancy
  - Offices
  - Maximum expected occupant load: 10
- Construction
  - Totally noncombustible concrete construction throughout

3. **Dispute**

The dispute between the Applicant and the Respondent concerns sufficiency of compliance with Articles 3.2.1.5., 3.2.2.2., 3.2.2.61., 3.4.2.1., & 3.4.4.1., and Sentences 3.2.1.1.(8), 3.2.2.11.(2), 3.2.8.2.(3) & 3.4.2.5.(1) the Building Code. The subject areas under dispute are as follows: i) the classification of the building; ii) the interpretation of the below grade process areas as storeys; iii) the requirement for sprinklering the building in its entirety; and, iv) the requirement for providing exits from every below grade process level.

4. **Provision of the Building Code**

Sentence 3.2.2.61. Industrial Buildings, Division 3, up to 6 Storeys

1. A building classified as Group F, Division 3 shall conform to Sentence (2) provided the building
   a. is not more than 6 storeys in building height,
   b. if unsprinklered, has a building area not more than the value in Table 3.2.2.Z., and
   c. if sprinklered, is not more than twice the area limits of Clause (b).
2. The building shall be of noncombustible construction, and
   . floor assemblies shall be fire separations with a fire- resistance rating of not less than 1 h,
   a. mezzanines shall have a fire-resistance rating of not less than 1 hr,
   b. roof assemblies shall have a fire-resistance rating of not less than 1 h, and
   c. all loadbearing walls, columns and arches shall have a fire-resistance rating not less than that required for the supported assembly.

Article 3.2.2.2.nbsp;nbsp;nbsp;nbsp;nbsp; Special and Unusual Structures

Structures which cannot be identified with the descriptions of buildings in Articles 3.2.2.16. to 3.2.2.62. shall be protected against fire spread and collapse in conformance with good fire protection engineering practice, such as described in the NFPA Fire Protection Handbook, Sixteenth Edition.

Sentence 3.2.1.1.(8).nbsp;nbsp;nbsp;nbsp;nbsp; Exceptions to Building Height in Storeys

3. Mezzanines, elevated walkways and platforms in Group F, Division 2 or 3 major occupancies need not be considered as storeys in calculating building height provided
    - the building is of noncombustible construction
    - except for Clause (c), the mezzanines, elevated walkways and platforms are intended solely for periodic service and maintenance, and
    - where they are intended to be occupied, no mezzanine, elevated walkways or platform shall have an occupant load more than 4 persons.

Article 3.2.1.5.nbsp;nbsp;nbsp;nbsp;nbsp; Fire Containment in Basements

4. Except as provided in Sentences (2) and 3.2.2.11.(2), basements shall be sprinklered or shall be subdivided into fire compartments not more than 600 m? (6460 ft?) in area by a fire separation having a fire-resistance rating not less than that required for the floor assembly immediately above the basement.
5. An open-air storey need not conform to Sentence (1).

Sentence 3.2.2.11.(2)nbsp;nbsp;nbsp;nbsp;nbsp; Storeys Below Ground

6. Where a building or portion thereof is erected entirely below the adjoining finished ground level and extends more than 1 storey below such ground level, the following minimum precautions against fire spread and collapse shall be taken:
    - except as provided in Sentence (3), basements shall be sprinklered,
    - floor assemblies below such ground level shall be constructed as a
        i. fire separation with a fire-resistance rating of not less than 3 h where the basements are occupied by Group E or Group F, Division 1 or 2 occupancies, and
        ii. fire separation with a fire-resistance rating of not less than 2 h where the basements are occupied by any other occupancy, and
    - all loadbearing walls, columns and arches shall have a fire-resistance rating not less than that required for the construction that they support.

Sentence 3.4.2.5.(1)nbsp;nbsp;nbsp;nbsp;nbsp; Location of Exits

7. Except as provided in Sentences (2), (3) and 3.3.2.4.(6), where more than one exit is required from a floor area, such exits shall be located so that the travel distance to not less than one exit as described in Article 3.4.2.4. shall be not more than
    - 25 m (82 ft) in any Group F, Division 1 occupancy,
    - 45 m (147 ft 8 in) in any sprinklered floor area that contains an occupancy other than Group F, Division 1
    - 40 m (131 ft 3 in) in any Group D occupancy,
    - 105 m (344 ft 6 in) in any floor area, served by a public corridor, in which rooms and suites are not separated from the remainder of the floor area by a fire separation, provided
        i. the public corridor has a width of not less than 9 m (29 ft 6 in)
        ii. the ceiling height in the public corridor is not less than 4 m (13 ft 1 in) above all floor surfaces,
        iii. the building is sprinklered, and
        iv. not more than one half of the required egress doorways from a room or suite open into the public corridor when the room or suite is required to have more than one egress doorway,
    - 60 m (196 ft 10 in) in any storage garage that conforms to the requirements of Article 3.2.2.60., and
    - 30 m (98 ft 5 in) in any other occupancy.

Sentence 3.2.8.2.(3)nbsp;nbsp;nbsp;nbsp;nbsp; Exceptions to Special Protection

8. Where a closure in an opening in a fire separation would disrupt the nature of a manufacturing process, such as a continuous flow of material from storey to storey, the closure for the opening is permitted to be omitted provided precautions are taken to offset the resulting hazard. (See Appendix A.).

Article 3.4.2.1.nbsp;nbsp;nbsp;nbsp;nbsp; Minimum Number of Exits

9. Except as provided in Sentences (2) to (4), and (6), every floor area as regulated in Article 3.4.1.1. shall be served by not less than 2 exits.

Article 3.4.4.1.nbsp;nbsp;nbsp;nbsp;nbsp; Fire-Resistance Rating of Exit Separations

10. Except as provided in Article 3.4.4.3 and Sentences(2), 3.3.5.5.(3) and 3.4.4.2(2), every exit shall be separated from each adjacent floor area by a fire separation having a fire-

resistance rating not less than that required for the floor assembly above the floor area and, where there is no floor assembly above, not less than that required by Subsection 3.2.2. for the floor assembly below, but in no case shall the fire-resistance rating be less than 45 min.

11. The fire-resistance rating for the fire separation in Sentence(1) need not be more than 2 h.
12. Where an exit stair in an assembly hall or theatre serves more than one balcony level, the exit stair shall be separated from the remainder of the building in conformance with Sentence(1).

Applicant's Position

The Applicant submitted the following information to support their position:

13. The Building Code, Sentence 3.2.2.11.(2) requires "Where a building or portion thereof is erected entirely below the adjoining finished ground level and extends more than 1 storey below such ground level, the following precautions against fire spread and collapse shall be taken:
    - except as provided in Sentence (3), basements shall be sprinklered..."

      The Building Code, Clause 3.2.2.62.(2)(a) requires "...floor assemblies shall be fire separations with a fire-resistance rating of not less than 2h, except that such floor assemblies are permitted to be reduced to fire separations with a fire-resistance rating of not less than 1 h in a storage garage with all storeys constructed as open-air storeys, ..."

Municipality's Position

The municipality advised that the entire plant should be sprinklered because the building includes multiple basement levels below grade and because there are unprotected equipment access openings at each basement level in the low lift pumping area.

Applicant's Position

Sprinklering is not required for the following reasons:

14. The landscaping grade changes depending where one is located in the plant and, therefore, the number of stories below grade also changes.

15. The berming of the superstructure at the western portion of the plant is no different than that of an exposed superstructure having a non-combustible roof and non- combustible walls with no windows. Room Nos. 8304 & 8305 at Elev. 83.5 m level. as such, can be considered to be the second floor of the plant. Exterior fire exits are provided at this level.
16. The 77.725 m elevation level can, therefore, be considered the ground floor.
17. The majority of the plant has only one basement level below the ground floor. Depending where one is in the plant, the first and only basement level can be encountered at the 70.8 m or 71.4 m, or 73.15 m, or 74.875 m elevation levels. In area, the above-mentioned floors make up 25.8% of the total basement footprint.
18. Only in the low lift pumping area of the plant is there multiple service levels. They are at the 73.15 m, 69.875 m and 66.6 m elevation levels. These levels are connected by two open staircases and have equipment access openings in each floor level to allow installation and removal of equipment. The low lift pumping area house large low lift pumps and small miscellaneous pumps. The small miscellaneous pumps have motors mounted on them. Otherwise all motors and electrical starters are housed at the ground floor level (Elev.77.725). There is no combustible load other than the insulation on the electrical wiring in the service levels. The Building Code, Sentence 3.2.8.2.(3) and A-3.2.8.2(3) allow non- sprinklering of the equipment access openings if the remainder of the facility is unsprinklered.

The entire low lift pumping area is designed to facilitate the production of drinking quality water. Equipment and piping must be readily accessible in the event of breakdown. The production of water cannot stop. Intermediate service levels were designed into the facility to provide an operator practical access to pumps and piping off high ceilings.

19. The Building Code, Clause 3.4.2.5.(1)(b) allows a 45 m travel distance between exits in any sprinklered floor area that contains an occupancy other than Group F, Division 1. The corridor for Room 8305 and 8304 at the Elev 83.5 m level house three stair exits (Nos. 3, 4, grid 1/D).

Municipality's Position

The municipality contends that the definition of sprinklered floor area requires the entire plant to be sprinklered, including the area above the filters, because the definition of floor area "means the space on any storey of a building between exterior walls and required firewalls..".

Applicant's Position

Sprinklering is required only in the corridor and not in the rest of the plant for the following reasons:

20. The intent of the Building Code is to ensure that all things that are combustible within firewalls and exterior walls do not catch on fire and hinder egress. The entire water plant including the corridor wall in question are non combustible. Open tanks of water on the other side of the corridor wall cannot catch on fire. If there is nothing to catch on fire there will be no egress hinderance. As such, sprinklering the entire plant would provide no practical benefit.
21. The only combustible load in the plant is the insulation on the electrical wiring.
22. Simcoe decided to sprinkler only the corridors in order to meet the allowable 45 m travel distance between exits.
23. One hour fire separations will be provided between sprinklered and non sprinklered areas.
24. The Building Code, Sentence 3.4.4.1.(10 requires ".. every exit shall be separated from each adjacent floor area by a fire separation having a fire-resistance rating not less than that required for the floor assembly above the floor area and, where there is no floor assembly above, not less than that required by Subsection 3.2.2. for the floor assembly below, but in no case shall the fire-resistance rating be less than 45 min."

Municipality's Position

The municipality advises that both Stair Nos.8 and 9 in the low lift area are required exits and should be enclosed and lead directly outdoors.

Applicant's Position

The Applicant understands that the intent of enclosing the staircases is to provide protected egress for people and a protected means for the fire department to enter the basement to fight fires. The Applicant believes that enclosing these stairs are not required because of the following reasons:

25. Two alternate accessible enclosed stairway exits are already provided in the basement level.
26. It is the Applicant's opinion that enclosing the stairs does not provide additional life safety due to the noncombustible nature of the construction and the extremely low risk.

In order to accommodate this request, major structural modifications are required.

27. The Applicant requested the building be reclassified from a F- 3 occupancy structure to that of a Special and Unusual Structure as per Article 3.2.2.2. of the Building Code.

Municipality's Position

The municipality's position is that because a portion of this building includes administrative offices, it therefore, cannot be considered a special and unusual structure in its entirety.

Applicant's Position

The Applicant's position is that, unlike some of the F-3 examples given in Appendix to the Building Code (A-3.1.2.A.), the water plant is a special and unusual structure because of the following reasons:

28. There typically is only one water plant in any City. The facility is designed for a 50 year life span, and, unlike factories or office towers, water plants are not built on a periodic basis.
29. The design of the building is unusual.
30. The landscaping and berming features are extremely unusual.
31. Fire protection measures in the administration area have been provided in accordance with the Building Code.
32. The entire plant is constructed of non-combustible materials.
33. The risk is extremely low because water cannot catch on fire.
34. NFPA 820 Standard for Fire Protection in Wastewater Treatment and Collection Facilities was prepared specifically for a wastewater treatment plant. "The need to develop NFPA 820 was based on fire or explosion incidents that, while infrequent, are relatively severe when they occur". The standard was developed for wastewater treatment plants because, unlike water plants, there are different fire and explosion hazards to consider. The following is a description of some typical wastewater treatment plant processes and the associated fire and explosion hazards that must be taken into account.
35. Prior to entering the plant pumping station, raw sewage is screened for rags and large objects before being pumped to primary clarifies. Settling of organic particles occur in the clarifies. Downstream liquid stream processes can include having the sewage enter aeration tanks, final clarifies and polishing filters before entering a water stream.

Raw sewage cannot catch on fire or cause an explosion unless gasoline, for eg. has been spilled by accident into the sewer and has reached the sewage plant in an undiluted state. To prevent this occurrence, NFPA 820 recommends sewage pumping stations be designed to have a physically separated wet well and dry well. All pumping equipment is located in the dry well. The separation prevents open sparks which may originate from equipment from coming into contact with the gasoline vapours in the sewage wet well. Raw sewage pumping stations typically have many stories below grade. In raw sewage pumping station drywells, NFPA 820 Table 2, Item 17, makes no special distinction for multi-level basements and recommends fire extinguishers, and not sprinklers, be provided as the minimum fire protection measure in dry well areas. Raw sewage pumping stations are typically constructed from non combustible building materials. The only combustible load would be the insulation on wiring. Risk of fire is extremely low.

36. Anaerobic sludge digesters are used to stabilize sewage sludge. A by-product of the process is explosive digester gas.
37. Dewatering of digested sewage sludge is a common process that is used to reduce the volume of sludge to be transported off site to landfill. Dewatering of sludge can make the sludge dry enough so that it is combustible. The NFPA in Quincy, Mass, advise that, unlike wastewater plants, there is no fire protection standard for water treatment plants. The American Water Works Association in Denver, Colorado, which is a North American association devoted to the advancement of water treatment and distribution, recommends the use of fire extinguishers and central alarm monitoring systems in large water plants. It is quite likely that no fire protection standard for a water treatment plant was developed because the risk is extremely low compared to some processes in a wastewater plant.
38. The Town has, in the very recent past, followed NFPA 820 and allowed the use of portable fire extinguishers as the only means of physical fire protection in a raw sewage pumping station which is currently under construction. In many ways, a raw sewage pumping station is similar to that of a water plant low lift pumping station. The difference is that, in a water treatment plant, all of the processes are housed under one roof. The Applicant advised that the municipality should consider applying NFPA 820 fire protection measures used for a raw sewage pumping station to the Ajax plant low lift pumping station. In such a case, only fire extinguishers would be required. The municipality's requirement to install sprinklers over and above the fire protection measures already designed into the Ajax Water Plant does not make sense because it

imposes a higher standard for fire protection for a water treatment plant than that for a "more hazardous" wastewater treatment plant.

5. **Chief Building Official's Position**

The Respondent submitted the following comments with respect to the specific areas of dispute:

0. Classification as a Special and Unusual Structure

This would appear to be an F-3 building for which design criteria is identified in 3.2.2.61. and therefore the designation as a special and unusual structure need not be applied. Inasmuch as more than 15% of the building floor area is assigned to occupancy by persons in administrative offices, it would not appear to be appropriate to consider this a special and unusual structure in entirety, and in any event there would not appear to be any recognized definitive alternate standard against which we could review this building.

1. Below grade storeys

The process floors would not appear to be exempt from the requirements of storeys under 3.2.1.1.(8) in that they are below the first storey and are therefore not within the context of building height to which this exemption refers. Below grade levels are inherently more potentially hazardous than comparably designed above grade facilities, therefore the acceptance of the entire below grade complex as one storey with interstitial mezzanines or platforms under this sentence would not appear to be appropriate.

2. Sprinklering

The requirement for sprinklering the complete floor areas in this building is due severally to:

- the process areas being contained in basements (3.2.1.5.)
- storeys being constructed below ground (3.2.2.11.(2))
- the travel distance to exits exceeding 30m (3.4.2.5.(1)), and
- openings contained in the 2 hr. floors between process storeys (3.2.8.2.(3)).

The below grade process areas are not provided with any sprinkler protection, and there is no alternate means of containment proposed between floor levels. The applicant has proposed to sprinkler only those portions of the building outside of the process areas where the travel distance of 30m is exceeded (and the administration area, to provide for

the interconnected floor space). The boundaries of the sprinklered areas include interior unrated partition walls, which condition does not constitute the sprinklering of the floor area where the travel distance is exceeded.

3. Exits

The below grade process floor areas at levels 66,600 and 69.875 are not provided with any separated exits (3.4.2.1., 3.4.4.1.). Persons occupying these areas will not have available to them at this level any protected means of egress should any unforeseen fire-related circumstances arise. Levels 73.150 and 77.725 are not provided with exits within applicable maximum travel distance limitations (3.4.2.5.(1)).

6. **Commission Ruling:**

It is the decision of the Building Code Commission that the building provides sufficiency of compliance with the requirements of the Building Code provided; the installed fire alarm system is connected to the fire department as per Sentence 3.2.4.7.(3) of the Building Code.

7. **Reasons:**
    0. The building can be considered a Special and Unusual Structure as per Building Code Article 3.2.2.2.
    1. The design of the building incorporates unusual berming features, complex design features with subsidiary administrative areas.
    2. The building is non-combustible construction containing very limited fuel load.
    3. The water treatment plant has a very low occupant load.
    4. Enclosed exits are well distributed around the perimeter of the treatment plant.
    5. The administrative areas of the building are sprinklered and separated from the chemical facilities by a 2 hour fire rated wall.
    6. The viewing and operators galleries are sprinklered and separated from the rest of the treatment plant by a 1 hour fire separation.
    7. Public tours of the facility will be supervised and limited in frequency, in the number of participants, and to certain areas of the building.
    8. Evidence provided indicates that NPFA 820, Standard for Fire Protection in Wastewater Treatment and Collection Facilities does not require sprinklering for facilities that pose more of a fire hazard than water treatment plants.
    9. Additional early warning of fire in the form of smoke and heat detectors have been provided.

10. Floor levels within the below grade areas are considered similar to work platforms as described in Sentence 3.2.1.1.(8).
11. Evidence provided suggests that no known water treatment plants in Ontario or Canada have been sprinklered.
12. Although a comprehensive risk analysis has not taken place, evidence provided by the Housing Development and Buildings Branch suggests that since 1983 there have been only a limited number of fires with low fire losses, no deaths and no injuries in water treatment plants due in large measures to low combustible content and non-combustible wall finishes.
13. The Housing Development and Buildings Branch intends to lead a task group to study the issue of the application of the Building Code to Water and Sewage Treatement Plants.

Dated at Toronto, this 15th day, in the month of October, in the year 1996, for application number 1996-48.

BCC Ruling No. 96-44-527

BUILDING CODE COMMISSION DECISION ON B.C.C. #96-44-527

IN THE MATTER OF Subsection 24(1) of the *Building Code Act, 1992.*

AND IN THE MATTER OF Articles 3.5.4.3., 6.2.3.2., and Sentence 3.1.5.14.(1) of the Revised Regulation of Ontario 1990, Regulation 61, as amended by O.Regs. 400/91, 158/93, 160/93, 383/94 and 20/95 (the "Building Code").

AND IN THE MATTER OF an application by Ms. Gabrielle McMillan, Manager of Finance and Administration, Canadian Mental Health Association, Windsor-Essex County Branch, Windsor, Ontario, for the resolution of a dispute with Mr. Edward Link, Chief Building Official, City of Windsor, concerning whether the ceiling plenum consisting of a 1 ?" wood roof deck, sprinkler system and smoke detectors provide sufficiency of compliance with Articles 3.5.4.3. 6.2.3.2., and Sentence 3.1.5.14.(1) of the Building Code at the Canadian Mental Health Association, Windsor-Essex County Branch, 1400 Windsor Avenue, Windsor, Ontario.

DATE OF RULING

September 26th, 1996

APPEARANCES

Mr. Randi Glos
Architect
Randi Glos Architect
Windsor, Ontario
Agent Representing Applicant

RULING

1. **The Applicant**

   Ms. Gabrielle McMillan, Canadian Mental Health Association is the holder of a permit under the Building Code Act, 1992 to renovate a one storey office (i.e Group D) building at 1400 Windsor Drive, Windsor, Ontario.

2. **Description of Constrution**

   The subject building is a one storey fully sprinklered Group D occupancy with a building area of approximately 2453 m² (26,406 ft²). It is built with a combination of combustible and noncombustible construction.

   The sprinkler system is electrically supervised and the fire alarm system will transmit directly to the local fire department in the event of a fire.

   A wood roof deck ceiling return-air plenum which consists of 1346 m² (14,486 ft²) will be sprinklered on both above and below the suspended ceiling in accordance with NFPA 13 standard.

The Applicant proposes to install additional smoke detectors within the return-air plenum that will shut down the air handling system when activated.

3. **Dispute**

The dispute between the Applicant and the Respondent concerns sufficiency of compliance with the Building Code. At issue is whether the ceiling plenum consisting of combustible material (1 ?" wood roof deck), sprinkler system and the smoke detectors provide an equivalent level of performance to that intended by the Building Code.

4. **Provision of the Building Code**

Article 3.5.4.3. Plenum Requirements

1. The concealed space between the ceiling and floor or ceiling and roof used as a plenum need not conform to Sentence 3.1.5.14.(1) and Article 6.2.3.2. provided
    a. all materials within the ceiling space have a flame- spread rating of not more than 25 and a smoke developed classification of not more than 50, except for
        i. tubing for pneumatic controls,
        ii. optical fibre cables and electrical wires and cables that exhibit a flame-spread of not more than 1.5 m (4 ft 11 in), a smoke density of not more than 0.5 at peak optical density and a smoke density not more than 0.15 at average optical density when tested in conformance with the Flame and Smoke Test in the Appendix to CSA C22.2 No. 0.3, "Test Methods for Electrical Wires and Cables" (FT6 Rating),
        iii. optical fibre cables and electrical wires and cables that are located in totally enclosed noncombustible raceways (see A- 3.1.4.3.(1)(b)(i) in Appendix A) and
        iv. single conductor electrical wires and cables that exhibit a vertical char of not more than 1.5 m (4 ft 11 in) when tested in conformance with the Vertical Flame Test - Cables in Cabletrough in Clause 4.11.4. of CSA C22.2 No. 0.3, "Test Methods for Electrical Wires and Cables" (FT4 Rating), and
    b. the supports for the ceiling membrane are of noncombustible material having a melting point not below 760?C (1400?F).
2. When the concealed space referred to in Sentence (1) is used as a return-air plenum and incorporates a ceiling membrane that forms part of the required fire-resistance rating of

the assembly, every opening through the membrane shall be protected by a fire stop flap which shall

a. stop the flow of air into the concealed space in the event of a fire,
b. be supported in a manner that will maintain the integrity of the ceiling membrane for the duration of time required to provide the required fire-resistance rating, and
c. conform to CAN4-S112.2-M, "Standard Method of Fire Test of Ceiling Firestop Flap Assemblies".

3. Asbestos paper shall not be exposed in supply and return-air systems.

Sentence 3.1.5.14. Combustible Ducts

4. Except as permitted by Sentence 3.5.4.3.(1), combustible ducts, including plenums and duct connectors, are permitted to be used in a building required to be of noncombustible construction provided such ducts and duct connectors

a. are used only in horizontal runs, and
b. are Class 1 conforming to Article 6.2.3.2.

Article 6.2.3.2. Materials in Air Duct Systems

3. Except as provided in Sentences (2) to (4) and in Article 3.5.4.3., all ducts, duct connectors, associated fittings and plenums used in air duct systems shall be constructed of steel, aluminum alloy, copper, clay, asbestos-cement or similar noncombustible material.
4. Ducts, associated fittings and plenums may contain limited amounts of combustible material provided they

a. conform to the appropriate requirements for Class 1 duct materials in CAN/ULC-S110-M, "Standard Methods of Test for Air Ducts",
b. conform to Article 3.1.5.14. and Subsection 3.1.9.,
c. are not used in vertical runs serving more than 2 storeys, and
d. are not used in air duct systems in which the air temperature may exceed 120?C (248?F).

5. Duct sealants shall have a flame-spread rating of not more than 25 and a smoke developed classification of not more than 50.
6. Duct connectors that contain combustible materials and that are used between ducts and air outlet units shall

. conform to the appropriate requirements for Class 1 air duct materials in CAN/ULC-S110-M, "Standard Methods of Test for Air Ducts",

a. be limited to 4 m (13 ft 1 in) in length,

b. be used only in horizontal runs, and

c. not penetrate required fire separations.

7. Materials in Sentences (1) to (4) which when used in a location where they may be subjected to excessive moisture shall have no appreciable loss of strength when wet and shall be corrosion-resistant.

5. **Applicant's Position**

The Applicant submitted that the intent of Article 3.5.4.3. of the Building Code is to prevent the spread of fire and smoke throughout the building as a result of a fire in the ceiling plenum.

The Applicant submitted that the sprinkler system and smoke detectors provide an equivalent level of performance that meets the intent of the Building Code.

The Applicant submitted that in Sentence 3.1.13.6.(2) and Sentence 3.1.13.7.(2) of the Building Code where a building is sprinklered, the requirements for flame spread rating and smoke development classification is considered to be met.

The Applicant submitted that the installation of smoke detectors to shutdown the air handling systems would provide an additional level of safety.

6. **Chief Building Official's Position**

he Respondent submitted that the ceiling and the roof deck for the existing building at 1400 Windsor Avenue is being used as a return air plenum for a new HVAC system.

The Respondent submitted that Article 3.5.4.3. specifically states that a concealed space between the ceiling and the roof in a building used as a plenum need not conform to Sentence 3.1.5.14.(1) and Article 6.2.3.2. provided that all materials in the space have a flame spread rating of not more than 25 and a smoke development classification of not more than 50.

The Respondent submitted that there is exposed wood decking in the ceiling space at 1400 Windsor Avenue. This material exceeds both these limits. The Building Code does not allow for trade offs such as sprinklers and/or smoke detectors in ceiling spaces to permit these spaces to be used as plenums where there are materials in the space which exceed these limitations.

The Respondent submitted that Article 2.7.2.2. of the Building Code does not allow for equivalents to be used in lieu of a prescribed Part 3 building system.

The Respondent did not attend the hearing.

7. **Commission Ruling:**

It is the decision of the Building Code Commission that the wood roof deck exposed to the plenum space provides sufficiency of compliance with Articles 3.5.4.3. and 6.2.3.2. and Sentence 3.1.5.14.(1) of the Ontario Building Code provided the plenum is sprinklered and equipped with smoke detectors that would shut down the HVAC systems and activate the building's fire alarm system.

8. **Reasons:**
    1. The Building is classified as Group D occupancy and is less than 30,000 sq. ft in building area, faces onto two streets and is one storey in building height.
    2. The addition of sprinklers in the plenum space significantly reduces the risk of fire spread.
    3. The installation of smoke detectors that upon activation shut down the HVAC systems significantly reduce the possibility of smoke spread in the event of fire.

Dated at Toronto, this 26th day, in the month of Sebtember, in the year 1996, for application number 1996-43.

BCC Ruling No. 96-43-526

BUILDING CODE COMMISSION DECISION ON B.C.C. #96-43-526

IN THE MATTER OF Subsection 24(1) of the *Building Code Act, 1992.*

AND IN THE MATTER OF Sentence 7.2.2.3.(3) of the Revised Regulation of Ontario 1990, Regulation 61, as amended by O.Regs. 400/91, 158/93, 160/93, 383/94 and 20/95 (the "Building Code").

AND IN THE MATTER OF an application by Mr. Don Duncan, CEO, YMCA - YWCA of Guelph, for the resolution of a dispute with Mr. Bruce Poole, Chief Building Official, City of Guelph, to determine whether not sloping the floor and locating the drain so that water from one head will flow over the area that serves another head in a group shower facility provides sufficiency of compliance with Sentence 7.2.2.3.(3) of the Building Code at the YMCA-YWCA of Guelph, 130 Woodland Glen Drive, Guelph, Ontario.

APPLICANT

Mr. Don Duncan, CEO YMCA-YWCA of Guelph
130 Woodland Glen Drive

APPEARANCES

Mr. David McAuley
Architect
J. David McAuley Architect Inc.
Guelph, Ontario
Agent Representing Applicant

Mr. John D. Peacock
Chief Plumbing Inspector
Corporation of City of Guelph
For the Respondent

RULING

1. **The Applicant**

   Mr. Don Duncan, CEO of YMCA-YWCA of Guelph, is the holder of a permit under the Building Code Act, 1992 to construct a YMCA-YWCA building at 130 Woodland Glen Drive, Guelph, Ontario.

2. **Description of Constrution**

   The building in question is a single storey, Group A, Division 2 assembly occupancy.

   At issue is whether the present arrangement of shower heads, combined with the sloping of the floor meets the requirements of Sentence 7.2.2.3.(3) of the Building Code.

3. **Dispute**

   The dispute between the Applicant and the Respondence concerns sufficiency of compliance with Article 7.2.2.3.(3) of the Building Code. At issue is the location of the drains and slope of the floor that would prohibit the water from one head from flowing over the area that serves another head in a group shower facility

4. **Provision of the Building Code**

   Sentence 7.2.2.3.(3) Showers

   3. Where two or more shower heads are served by a shower drain, the floor shall be sloped and the drain located so that water from one head cannot flow over the area that serves another head.

5. **Applicant's Position**

   The Applicant submitted that the height of the shower heads for the spray pattern makes it impossible to control flow from any head to a specific drain especially when bodies splash water randomly. The Applicant submitted that this would require full height partitioning & one floor drain per head. The intent of Sentence 7.2.2.3.(3) of the Building Code is with respect to safety & the ability to clean & disinfect surfaces.

6. **Chief Building Official's Position**

   The Respondent submitted that more than two shower heads are served by one shower drain and the floors are improperly sloped to prevent water from one head flowing over the area that serves another head.

7. **Commission Ruling:**

   It is the decision of the Building Code Commission that the shower heads do not comply with the provisions of Sentence 7.2.2.3.(3) of the Building Code in the following locations:

   Room 213 heads 2, 4, 8
   Room 217 heads 1 or 2 and 3 or 4

8. **Reasons:**

   Evidence presented indicates that the heads identified have spray patterns so that water from one head can flow over the area that serves another head in the group showers. Solutions may include elimination of shower heads, changing spray patterns or the installation of other devices or equipment to direct flow.

Dated at Toronto, this 15th day, in the month of October, in the year 1996, for application number 1996-46.

BCC Ruling No. 96-42-525

BUILDING CODE COMMISSION DECISION ON B.C.C. #96-42-525

IN THE MATTER OF Subsection 24(1) of the *Building Code Act, 1992.*

AND IN THE MATTER OF Sentence 9.10.14.12.(3) and Article 9.10.14.5. of the Revised Regulation of Ontario 1990, Regulation 61, as amended by O.Regs. 400/91, 158/93, 160/93, 383/94 and 20/95 (the "Building Code").

AND IN THE MATTER OF an application by Mr. Robert Root, Owner, Peterborough, Ontario, for the resolution of a dispute with Mr. Jeff Chalmers, Chief Building Official, City of Peterborough, concerning whether the windows that result from the conversion of a second floor balcony to a sunroom addition provides sufficiency of compliance with Sentence 9.10.14.12.(3) and Article 9.10.14.5. of the Ontario Building Code at 426 Park Street North, Peterborough, Ontario.

APPEARANCES

Mr. Robert Root
Peterborough, Ontario
The Applicant

Ken Guthrie, Building Inspector
City of Peterborough
Agent for the Respondent

RULING

1. **The Applicant**

   Mr. Robert Root, Owner, is a holder of a permit under the Building Code Act, 1992 to construct a sunroom addition to a single family dwelling (i.e. house) at 426 Park Street North, Peterborough, Ontario.

2. **Description of Constrution**

   The subject building is a 2 storey home, and the proposed construction is the addition of a sunroom enclosure on the top of an existing second storey balcony.

   The windows in the subject exposing building face are approximately 18 ft² in area.

3. **Dispute**

   The dispute between the Applicant and the Respondent concerns sufficiency of compliance with the technical requirements of Sentence 9.10.14.12.(3) and Article 9.10.14.5. of the Building Code. At issue is whether the windows in the proposed conversion of a second floor balcony to a sunroom addition may be permitted at a limiting distance of 0.96m from the property line, as opposed to the required 1.2 m.

4. **Provision of the Building Code**

Sentence 9.10.14.12.(3) Exposing Building Face of Houses

"Glazed areas in the exposing building face referred to in sentence (1) shall not be permitted if the limiting distance is less than 1.2 m (3 ft 11 in) and shall be limited in conformance with the requirements for glazed areas in Table 9.10.14.A. where the limiting distance is 1.2 m (3 ft 11 in) or greater."

Article 9.10.14.5. Openings in Walls Having a Limiting Distance Less than 1.2 m

"Openings in a wall having a limiting distance of less than 1.2 m (3 ft 11 in) shall be protected by closures, of other than wired glass or glass block, whose fire protection rating is in conformance with fire-resistance rating required for the wall. (See Table 9.10.13.A.)"

5. **Applicant's Position**

The Applicant submitted that the intent of Sentence 9.10.14.12.(3) & Article 9.10.14.5. of the Building Code can be accommodated because: there is a driveway and lawn between the adjacent buildings; the nature of the building and lot makes it unlikely that additions will occur on the adjacent property; and the proposed limiting distance is very close to the required 1.2 m.

6. **Chief Building Official's Position**

The Respondent submitted that the proposed construction does not comply with Article 9.10.14.1 and Table 9.10.14.A. which do not permit unprotected openings and that the openings would be permitted if they were protected with closures in accordance with the Building Code.

7. **Commission Ruling:**

It is the decision of the Building Code Commission that the window opening of approximately 18 sq.ft. provides sufficiency of compliance with the requirements of Sentence 9.10.14.12.(3) of the Building Code on the provision that the existing windows in the basement area in the exposed building face are closed by material having a 3/4 hour fire resistance rating.

8. **Reasons:**

The Building Code allows transfer of existing areas of unprotected openings on the same exposing building face to be closed and transferred as permitted in Part 11 of the Building Code.

Dated at Toronto, this 31st day, in the month of October, in the year 1996, for application number 1996-49.

The Respondent

RULING

1. **The Applicant**

   Mr. Harvey Forde, Wesley-Robins Retirement Village Inc. is an Applicant for a permit under the Building Code Act, 1992 to construct a three storey building (i.e. Block A) that forms part of a retirement village at 242 First Avenue North, Welland, Ontario.

2. **Description of Constrution**

   The Applicant is proposing to construct a three storey residential building that forms part of a retirement village adjacent to an existing Church. A severance is proposed that will create a new property line between the Church and the residential building. As a result of the proximity of the new property line the windows on the west wall of the new residence are restricted to the amounts permitted in Table 3.2.3.A. of the Building Code.

   The Church does not have any unprotected openings in its adjacent wall and the proposed residential building is to be sprinklered.

3. **Dispute**

The dispute between the Applicant and Respondent concerns sufficiency of compliance with Articles 3.2.3.1., 3.2.3.5., 3.2.3.6., 3.2.3.7., and 3.2.3.8. of the Building Code. At issue is the spatial separation and percentage of window openings in the west Exposing Building Face of Block A at the Wesley-Robins Retirement Village.

4. **Provision of the Building Code**

Article 3.2.3.1. Limited Distance and Area of Unprotected Openings

1. Except as provided in Articles 3.2.3.9. to 3.2.3.11, the area of unprotected openings shall not be more than that set forth in Tables 3.2.3.A. or 3.2.3.B. for the limiting distance applicable to the exposing building face under consideration. (See A-3, Fire Fighting Assumptions in Appendix A.)
2. The area of the unprotected openings in an exposing building face shall be the aggregate area of unprotected openings expressed as a percentage of the area of the exposing building face in Tables 3.2.3.A. and 3.2.3.B. (See Sentence 3.2.3.2.(1).)
3. For the purposes of determining the type of construction and cladding and the fire-resistance rating of an exterior wall, the exposing building face shall be taken as the projection of the exterior wall onto a vertical plane located so that no portion of the exterior wall of the building or of a fire compartment, if the fire compartment complies with the requirements of Sentence 3.2.3.2.(1), is between the vertical plane and the line to which the limiting distance is measured and, for these purposes, the area of unprotected openings shall be determined from Table 3.2.3.A. or Table 3.2.3.B.
4. For the purposes of determining the actual percentage of unprotected openings permitted in an exterior wall, the location of the exposing building face is permitted to be taken at a vertical plane located so that there are no unprotected openings between the vertical plane and the line to which the limiting distance is measured. (See Appendix A.)
5. Where fire fighting facilities cannot reach the building within 10 min of the alarm being received, the limiting distance shall be doubled.

Article 3.2.3.5. Wall with Limiting Distance Less Than 1.2 m

Openings in every wall that has a limiting distance of less than 1.2 m (3 ft 11 in) shall be protected by closures, of other than wired glass or glass block, whose fire-protection rating is in accordance with Table 3.1.8.A. for the fire-resistance rating required for the wall.

Article 3.2.3.6. Combustible Projection Restrictions

Except for buildings containing 1 or 2 dwelling units only, combustible projections on the exterior of a wall that are more than 1 m (3 ft 3 in) above ground level, such as balconies, platforms, canopies, eave projections and stairs, and that could expose an adjacent building to fire spread, shall not be permitted within 1.2 m (3 ft 11 in) of a property line or the centre line of a public way, or within 2.4. m (7 ft 10 in) of a combustible projection on another building on the same property.

Article 3.2.3.7. Construction of Exposing Building Face

6. Except as permitted in Articles 3.2.3.9. and 3.2.3.10., where a limiting distance shown in Table 3.2.3.A. for a Group A, B, C, D or Group F, Division 3 occupancy classification is such as to permit an exposing building face to have unprotected openings of
    a. not more than 10 percent of the exposing building face, the exposing building face shall be of noncombustible construction having a fire-resistance rating of not less than 1 h and be clad with noncombustible cladding,
    b. more than 10 percent but not more than 25 percent of the exposing building face, the exposing building face shall have a fire-resistance rating of not less than 1 h and be clad with noncombustible cladding, and
    c. more than 25 percent but less than 100 percent of the exposing building face, the exposing building face shall have a fire-resistance rating of not less than 45 min.
7. Except as permitted in Article 3.2.3.9., where a limiting distance shown in Table 3.2.3.B. for a Group E, or Group F, Division 1 or 2 occupancy classification is such as to permit an exposing building face to have unprotected openings of
    a. not more than 10 percent of the exposing building face, the exposing building face shall be of noncombustible construction having a fire-resistance rating of not less than 2 h and be clad with noncombustible cladding,
    b. more than 10 percent but not more than 25 percent of the exposing building face, the exposing building face shall have a fire-resistance rating of not less than 2 h, and be clad with noncombustible cladding, and
    c. more than 25 percent but less than 100 percent of the exposing building face, the exposing building face shall have a fire-resistance rating of not less than 1 h.
8. In addition to the requirements of Sentences (1) and (2), where foamed plastic insulation is used in an exterior wall of a building more than 3 storeys in building height
    a. the insulation shall be protected on the exterior surface by
        i. concrete or masonry not less than 25 mm (1 in) thick, or

ii. noncombustible material that will remain in place for not less than 15 min when tested in conformance with CAN4-S101-M, "Standard Methods of Fire Endurance Tests of Building Construction and Materials", or

iii. the wall assembly shall conform to Article 3.1.5.5. where the protection in Clause (a) is not provided. (See Appendix A.)

Article 3.2.3.8. Protection of Structural Members

2. Structural members, such as beams, columns and arches placed wholly or partly outside an exterior face of a building and 3 m (9 ft 10 in) or more from the property line or centre line of a public thoroughfare need not be protected from exterior fires.
3. Structural members in Sentence (1) that are less than 3 m (9 ft 10 in) from the property line or centre line of a public thoroughfare shall be protected from exterior fire by fire protection having a fire-resistance rating not less than that required for their protection from inside fires in conformance with Articles 3.2.2.16. to 3.2.2.62., or by fire protection having a fire-resistance rating of not less than 1 h, whichever is the greater.
4. Structural members of heavy timber construction such as beams, columns and arches placed wholly or partly outside an exterior face of a building and 3 m (9 ft 10 in) or more from the property line or centre line of a public thoroughfare need not be covered with noncombustible cladding.

5. **Applicant's Position**

The Applicant submitted the following information and rationale concerning the acceptance of the spatial separation and percentage of window openings in the west face of Block A:

The Wesley United Church is on a parcel of land that is considerably larger in area than the church requires. Almost all of the land was given to the Church by Clarence and Clarice Robins.

Mr. Robins died some years ago and Mrs. Clarice Robins died in 1992 after making a will leaving the bulk of her substantial estate to the Church on condition that a senior citizen residence be built upon the Church lands.

The Church proceeded to incorporate a non-share capital charitable corporation, (Westley-Robins Retirement Village Inc.) to build and operate the retirement community. The members of

the corporation are the members of the Church plus such other persons (such as the executor of Clarice Robins' estate) as are admitted to membership in the corporation.

The Church and the corporation decided to sever the property of the retirement complex from the Church property so that any mortgage financing could be done by the corporation on its own property without involving the Church. The consent to sever has been granted but the deed has not yet been registered.

The registration of the deed will result in a new boundary line being created between the Church property and the retirement complex. It is this new boundary line that creates a problem for the retirement complex in that it greatly restricts the area of unprotected openings (windows) in the west wall of Building A. If the boundary between the two properties did not exist, the limitation on the area of unprotected openings would not apply to those parts of the west wall of Building A which do not directly face the Church building.

Unprotected openings near boundaries are limited presumably because with separate and distinct ownerships on each side of the boundary, neither owner could control the use on the opposite side of the boundary.

In this case, however the members of one body are the members of the other and each draw their officers, directors, elders and trustees from the same pool of members. Also, neither body can dispose of its property without the consent of the United Church of Canada.

The zoning for each property is site-specific and will be the subject of a single site plan agreement covering both properties so that neither the use of the properties not any change in, or addition to any building or additional buildings can be made or erected without an amendment to the site plan agreement and/or zoning by-law which requires the approval of the City of Welland.

The creation of the new boundary will not increase the danger from fire in the future on the south side of the Church since the land there (parts 6, 15 and 4 on Plan 59R9550) are subject to a permanent easement for vehicular and pedestrian traffic and because of this nothing can be built upon it. Each of the property owners also has an easement for parking in areas designated for that on the other's property.

There is little danger of fire crossing from the Church to Building A and vice versa because the Church building will have no unprotected openings in its easternmost wall. Building A is to be sprinklered.

There should be no increase in fire danger in the future for that part of the property north of the church building because as pointed out above, it cannot be built upon without an amendment to the site plan agreement or zoning by-law or both and those amendments would require the approval of the City of Welland. The City would take such things as spatial separation into consideration on deciding whether to grant such approval.

The Chief Building Official expressed some reservations over the City's ability to control future separation problems even though its approval would be required to any site plan or zoning by-law amendment. To solve this the municipality has suggested that the site plan agreement contain the following two paragraphs and our clients are agreeable to their inclusion:

i. "The owners agree to construct the exterior wall on the west face of Block A in accordance with the spatial separation requirements of the Ontario Building Code or the Ontario Building Code Commission".
ii. "The owners also agree not to construct any future buildings or building additions facing the west face of Block A unless the spatial separation requirements are met for both buildings as if they were constructed on the same property.

The chance of either of the two properties being used for something other than their present and intended uses is so remote as to be virtually non-existent. Even if the corporation ceases to exist, it is written into its Letters Patent of Incorporation as amended that, after payment of debts, all its property and assets are to become vested in the United Church of Canada or a charitable organization for the purpose of operating a seniors residence in Welland.

For these reasons the Applicant respectfully requested that the Commission grant relief from the limitations of Subsection 3.2.3. of the Building Code.

6. **Chief Building Official's Position**

The Respondent submitted that the west exposing building face of Block A is approximately 2.5 m or less to a property line (depending on which fire compartment is considered). The west exposing building face contains a significant amount of glazing that is not permitted by the Building Code.

The Respondent stated that he supported the proposal due to the following reasons:

. The subject building is fully sprinklered.

i. The east face of the existing Church is constructed of solid masonry.
ii. The chances of another building being constructed on the property is remote.
iii. The applicant has agreed to register the aforementioned clauses on the title of the property.

The Respondent does not have the authority to accept a deviation from the Building Code and the proposal does not fall within the scope of Section 2.7 of the Building Code.

7. **Commission Ruling:**

It is the decision of the Building Code Commission that the spatial separation of the residential building provides sufficiency of compliance with Articles 3.2.3.1., 3.2.3.5., 3.2.3.6, 3.2.3.7., and 3.2.3.8. of the Building Code, provided that the control of construction on the adjacent lands and where an exposure hazard exists is through limitations included in the site plan agreement and registered on title of both properties.

8. **Reasons:**

. The residential building is sprinklered throughout.
i. Evidence was presented that the exposed building facing of the Church on the adjacent property is constructed as a 2 hour fire wall.
ii. If the two properties were considered as one, and no severance had taken place the exposure hazards would not exist.
iii. It is the opinion of the Building Code Commission that the siting of the building does not present a fire exposure hazard.

Dated at Toronto, this 26th day, in the month of September, in the year 1996, for application number 1996-47.

AND
Mr. Steve Penna, Plan Review Supervisor
City of Vaughan
The Respondent

RULING

1. **The Applicant**

   The Applicant is a holder of a permit under the Building Code Act, 1992 to construct seven townhouse buildings known as the Emerald Gate Townhomes at 151 Towngate Drive, Thornhill, Ontario,

2. **Description of Constrution**

   The project consists of 7 separate buildings of which 6 are linked by a single level underground garage. Two of the buildings have a 45 degree angled exterior wall and bay type window assembly on either side of a 2 hour fire separation. One building has this exterior configuration occurring in two locations and the other has it occurring in three locations. A total of ten dwelling units are affected.

The municipality is requiring the exterior wall of each compartment within the calculated distance "Do" to have the same fire resistance rating as the 2 hour fire separation between dwelling units.

3. **Dispute**

The dispute between the Applicant and the Respondent concerns sufficiency of compliance with the technical requirements of Sentences 3.2.3.14.(1) & (2) of the Building Code. At issue is whether the bevelled side of a bay window is a wall or exposing building face of a fire compartment and if the portion of the exterior wall between such windows in each suite requires a fire resistance rating at least equal to the rating required for the interior demising wall.

4. **Provision of the Building Code**

Sentences 3.2.3.14.(1) & (2) Wall Exposed to Another Wall

1. Except as provided in Sentences 3.2.3.13.(1) and 3.2.3.20.(4), where an opening in an exterior wall of a fire compartment is exposed to an opening in the exterior wall of another fire compartment, and the planes of the 2 walls are parallel or at an angle of less than 135?, measured from the exterior of the building, the openings in the 2 fire compartments shall be separated by a distance at least equal to D? where

2. D? = 2D - (?/90 x D), but in no case less than
3. 1 m (3 ft 3 in)

where

D = the greater required limiting distance for the exposing building faces of the 2 fire compartments, and

? = the angle made by the intersecting planes of the exposing building faces of the 2 fire compartments, (in the case where the exterior walls are parallel and face each other, ? = 0?).

4. The exterior wall of each fire compartment in Sentence (1) within the distance, D?, shall have a fire-resistance rating not less than that required for the interior vertical fire separation between the compartment and the remainder of the building.

5. **Applicant's Position**

The Applicant submitted the following rationale as to why the bay windows of adjacent suites (not separated by a firewall) may be found acceptable under the Building Code:

The requirements of the Article 3.2.4.14. of the Building Code originally applied only to the exterior walls of fire compartments that met at a firewall. The requirement was extended to walls of separate fire compartments (not necessarily separated by a firewall) in the 1983 Building Code (based on changes made in the 1980 National Building Code).

Depending on the design specifics and variable code interpretation, this change has at times proved problematical for design of multi- unit residential buildings and inquiries have been made through a committee of the Ontario Association of Architects to the Canadian Code Centre (CCC). The CCC has indicated that there is no record of why the requirement was extended to walls of adjacent fire compartments meeting at a fire separation; it is presumed that the rationale implicit in the requirement for firewalls was extended to these other situations.

For the case at hand, the exterior walls of the two dwelling units are in the same plane. The bay windows (which extend as projections of the floor from floor to ceiling) are, in effect, "bumps" in the exterior exposing building face of the two dwelling units. These "bumps" do not extend from the full height of the dwelling unit; they project from the walls of the second and third floors of the dwelling units but not from the first storey or the attic gable. The Applicant regards these "bumps" as minor articulations in the exterior of each dwelling unit.

The Applicant submitted that the building could be designed with the completed glazed exterior walls of adjacent fire compartments meeting at an angle of 135 degrees. The glazed openings of one fire compartment could be no more than 3 or 4 inches from the glazed opening of the adjacent fire compartment and there would be no restriction on the proximity of the glazing or the amount of glazing. A fire plume emanating from one compartment in the vicinity of the exterior angle between walls would be immediately in front of windows of the adjacent compartment.

The Applicant submitted that the design of the Emerald Gate Townhomes separates the glazing of adjacent units (measured at the point where there is mutual exposure) at least 5 feet. The total projected width of the mutual exposure (glazing to glazing, measured at right angles to the brick face of the building between the window units) is some 13 inches. This is a less hazardous situation than is permitted by the lack of any restriction in the code of the vertical separation of windows, storey to storey, where a fire plume emanating from a window opening in the lower storey may be directly exposed to the upper storey window.

The Applicant submitted that on the basis of the 135 degree angle between the plane of the face brick and each of the bevelled sides of the bay windows, there should be no impact on the rating of the wall behind the face brick between the bay windows.

The Applicant further submitted that if the bevelled sides of the Emerald Gate Townhome bay windows which oppose one another across the end of the demising wall were to be window openings governed by Sentence 9.10.12.4.(1) of the Building Code; the as-built situation would be straight forwardly acceptable.

The scale of the building, the relationship of windows and storeys to grade and the general configuration of the dwelling units of the Emerald Gate Townhome project are entirely consistent with buildings one may evaluate under Part 9 of the Code.

The Applicant submitted that information provided by the City of Vaughan Fire Department demonstrated that in the event of a fire the time for smoke detector activation will be some 92 seconds and that, at most, a 1.5 minute evacuation time would be required for a dwelling unit. Flashover, according to the model used by the Fire Department would occur some 667 seconds (11 minutes) after the start of a fire, which is well beyond the time required for smoke alarm activation and evacuation of the dwelling unit. The Fire Department response time of 4 minutes plus evacuation time would still be expected to be well within the time limit for flash over in a dwelling unit. Occupants of both the unit containing the fire and adjacent units would, therefore, be expected to be evacuated before flashover occurred.

The Applicant submitted that it is most unlikely that there will be any hazard of fire exposure from one bay window to an adjacent bay window prior to flashover.

The Applicant submitted that with automatic detection of fire in a suite, and a 4 minute response time be the Fire Department, it is expected that fire suppression activities could begin in a time frame which would prevent any involvement of a neighbouring dwelling unit due to fire exposure from the bevelled edge of the bay window in an adjacent compartment containing fire.

The Applicant submitted that on this basis, the bay window certainly does not represent a fire hazard to life safety or a significant hazard in respect of potential for property damage of a neighbouring unit.

6. **Chief Building Official's Position**

The Respondent submitted that Sentences 3.2.3.14.(1) and (2) of the Building Code requires that the exterior wall of each fire compartment within the calculated distance "Do" have the same fire resistance rating as the 2 hour fire separation between the dwelling units.

The Respondent submitted that the two townhouse buildings in question are classified under Article 3.2.2.34. of the Building Code. The floor assemblies are required to be constructed as fire separations with a fire resistance rating of 45 minutes. Sentence 3.3.4.2.(2) of the Building Code waives this requirement if the distance between the lowest floor and the uppermost floor is not greater than 6 m (19ft 8 in). This height is exceeded in six of the buildings in this development.

The Respondent submitted that he agreed to waive the required 45 minute fire resistance rating of the floors within each dwelling unit, if the units were separated from one another by a concrete block fire separation with a 2 hour fire resistance rating.

The Respondent submitted that an inspection on August 26, 1996 confirmed that the angle of the windows and wall is actually 45 degrees and the distance between the openings is 1.23 m (4 ft 1/2 in).

7. **Commission Ruling:**

It is the decision of the Building Code Commission that the bevelled sides of the bay windows in separate fire compartments provide sufficiency of compliance with Sentence 3.2.3.14.(1) of the Building Code provided exterior walls between such windows have a one hour fire resistance rating.

8. **Reasons:**

i. For similar buildings under Part 9 of the Building Code, Article 9.10.12.4 permits window openings in walls that meet at an external angle of less than 135 degrees where the horizontal distance from one opening in one wall to another opening in another wall exceeds 1.2 m (3' 11").

ii. The dwelling units are separated from each other at common walls by masonry partitions having a 2 hour fire resistance rating.

iii. The bay window configuration applies to a limited number of dwelling units within the complex.

d) The local fire department analysis indicates that the times for detection, evacuation, and fire department response are well below time for flashover to occur.

e) No evidence was provided by either party of significant incidence of fire spread with this window configuration.

Dated at Toronto, this 11th day, in the month of September, in the year 1996, for application number 1996-44.

BCC Ruling No. 96-39-522

BUILDING CODE COMMISSION DECISION ON B.C.C. #96-39-522

IN THE MATTER OF Subsection 24 (1) of the *Building Code Act, 1992*.

AND IN THE MATTER OF Sentence 9.8.3.1.(1) and Article 9.8.5.2. of "the Building Code" (Ontario Regulation 419/89 as amended by Ont. Reg. 183/88, 581/88, 11/89 and 115/89)

AND IN THE MATTER OF an application by Mr. Dominic D'Eri for the resolution of a dispute with Ms. Pamela Coburn, Chief Building Official, City of Toronto concerning whether the width of the interior stairway provides sufficiency of compliance with Sentence 9.8.3.3.(2). of the Ontario Building Code at 49 Poulette Street, Toronto, Ontario.

RULING

1. **The Applicant**

   Mr. Dominic D'Eri, Owner, is a person to whom an order to comply has been issued under the *Building Code Act, 1992* to construct a single unit residential building at 49 Poulette Street, Toronto, Ontario.

2. **Description of Construction**

   The subject building is a 3 storey single unit residential house of combustible construction and a building area of 195 square metres (2,094 sq ft). A single exit stair extending from the basement to the third floor is provided at the south-west corner of the building.

3. **Dispute**

   The dispute between the Applicant and Respondent concerns sufficiency of compliance with Sentence 9.8.3.3.(2) of the Building Code. At issue is the proposed use of a stair which varies in width from 760 mm to 785 mm, as opposed to the stair shown on the approved set of drawings which has a code complying width of 836.6 mm (2 ft 10 in).

4. **Provisions of the Building Code**

   9.8.3.3.(2) Stair Width

   (2) At least 1 stairway between each floor level in a dwelling unit shall have a minimum width between wall faces of not less than 860 mm (2 ft 10 in)."

5. **Applicant's Position**

The applicant stated that the building was redesigned to provide for a thicker exterior wall but that the outside dimensions were not adjusted resulting in the interior stair being 51 to 102 mm (2 to 3 in) narrower. The Applicant further submitted that the stairs are within a single family dwelling and have worked sufficiently for a period of time.

6. **Chief Building Official's Position**

The Respondent submitted that the interior stair leading from the basement to the third floor varies in width from 760 mm to 785 mm and varies from Sentence 9.8.3.3.(2) and the approved permit plans. The Respondent further submitted that because the construction was for a new building the stairs could have and should have provided the minimum required width of 860 mm.

7. **Commission Ruling**

It is the decision of the Building Code Commission that the width of the interior stair ranging from 760 mm to 785 mm does not provide sufficiency of compliance with Sentence 9.8.3.3.(2) of the Building Code.

8. **Reasons:**

The Applicant did not provide persuasive evidence in support of sufficiency of compliance with the Building Code.

Dated at Toronto this **11th** day in the month of **March** in the year **1997** for application number **1996-42.**

The Respondent

RULING

1. **The Applicant**

   Mr. Charles Byrne, Charles Byrne Construction, is the holder of a permit under the *Building Code Act, 1992* to construct a one storey single family dwelling (i.e. house) on Lot 22, Crestview Drive, Huntsville, Ontario.

2. **Description of Construction**

   The subject building is a one storey house with a slab-on-ground foundation. The warm-air supply outlets of the forced air heating system are installed with the main ducts located under the ceiling and the insulated branch lines in the attic space.

3. **Dispute**

   The dispute between the Applicant and the Respondent concerns sufficiency of compliance with Article 6.2.4.6. of the Building Code. At issue is whether the warm air supply system may be installed above the ceiling instead of in the concrete slab-on-ground.

4. **Provisions of the Building Code**

   Article 6.2.4.6. Concrete Slabs-on-Grade

   Warm-air supply systems for residential buildings built on concrete slabs-on-ground shall be installed in the slab and shall be of the perimeter loop type or radial perimeter type.

5. **Applicant's Position**

The Applicant submitted that the heating system for the house is a forced air gas system that blows heat from the ceiling level rather than the floor level. The supply vents are located over the windows.

The Applicant submitted that due to ground conditions at the site during construction it was not possible to install ducting in the slab-on-ground. Therefore, numerous insulating procedures were employed to super insulate the house.

The Applicant submitted that the home is insulated under the concrete slab and along the sides of the slab 1.22 m (4 ft) out from the perimeter of the building. The walls contain R21 insulation and the ceiling has an R60 blown cellulose blanket.

The Applicant stated that the heating system is designed for the minimum thermal insulation valves identified in the Building Code.

6. **Chief Building Official's Position**

The Respondent submitted that although the current installation does not conform to Article 6.2.4.6. of the Building Code it is his opinion that the installation meets the intent of the Building Code.

The Respondent states that the increased level of insulation in the attic and under the slab compensates for supply air vents being installed in the ceiling.

7. **Commission Ruling**

It is the decision of the Building Code Commission that providing warm air supply at the ceiling instead of at the concrete slab-on-ground demonstrates sufficiency of compliance with Article 6.2.4.6. of the Building Code provided supplementary baseboard heating is installed beneath windows in each bedroom and bathroom with a total capacity not to exceed 10% of the total heat loss of the building.

8. **Reasons:**

i) Insulation levels in the attic and floor slab significantly exceed those required by the Building Code.

ii) An open concept (living, dining, kitchen) plan has been used.

iii) Evidence was presented that the furnace capacity is well in excess of the building's heat loss.

iv) Supply registers have been provided over windows.

Dated at Toronto this **26th** day in the month of **September** in the year **1996** for application number **1996-41**.

RULING

1. **The Applicant**

   Mr. W.E. (Ted) Wilson, Project Architect, Totten Sims Hubicki Associates, Cobourg, is an applicant for a permit under the Building Code Act, 1992 to convert a former indoor swimming pool to a student lounge at the Sir Sandford Fleming College, 599 Brealey Drive, Peterborough, Ontario.

2. **Description of Constrution**

   The subject of the dispute is the new student centre at Sir Sandford Fleming College. The building is classified as an Assembly Occupancy, Division 2 (i.e. A-2). The college is 3 storeys in building height and includes a basement. The building area is 9982 m^2 (107,445 ft^2). The

building is of noncombustible construction, and contains a fire alarm system and a standpipe and hose system. The building is not protected by a automatic sprinkler system.

The area being renovated was formerly a indoor swimming pool which is proposed to be a student lounge. The bottom of the pool is being lowered to the level of the basement, creating a 2 storey lounge comprising the basement and lounge level. The two levels of the lounge are proposed to be connected by open stairs with no fire separation between the upper and lower floor areas. However, a 1 hour fire separation is proposed between the interconnected floor space and the remainder of the building.

3. **Dispute**

The dispute between the Applicant and Respondent concerns the sufficiency of compliance with the technical requirements of Sentence 3.2.8.2.(6) of the Building Code. At issue is whether the interconnected floor space designated as student lounge need be protected by an automatic sprinkler system.

4. **Provision of the Building Code**

Sentence 3.2.8.2.(6) Exceptions to Special Protection

6. An interconnected floor space need not conform to the requirements of Articles 3.2.8.3. to 3.2.8.11. provided
    a. the interconnected floor space consists of the first storey, and the storey next above or below it, but not both,
    b. the interconnected floor space is sprinklered, and
    c. the interconnected floor space contains only Group A, Division 1 or 2, Group D, Group E, or Group F, Division 3 major occupancies.

5. **Applicant's Position**

The Applicant submitted that the interconnected floor space designated as Student Lounge should be considered as not requiring sprinklering based on the precedent of non-sprinklered interconnected floor space in the existing building.

6. **Chief Building Official's Position**

The Respondent submitted that the Applicant is proposing an unsprinklered interconnected floor space consisting of the basement and the storey above, and proposes to separate the

interconnected floor space from the remainder of the building by a 1 hour fire separation in lieu of sprinklers.

The Respondent submitted that the interconnected floor space must be sprinklered, for the following reasons:

vi. Sentence 3.2.8.2.(6) of the Building Code requires a interconnected floor space to be sprinklered,
vii. the proposed 1 hour fire separation between the lounge and the remainder of the building does not provide relief from having to sprinkler the interconnected floor space. It provides relief from having to sprinkler the entire storey; and,
viii. although both levels of the lounge are served by adequate exits, they cannot be viewed as providing relief from the requirements for the interconnected floor spaces.

The Respondent submitted that the existing building contains what appears to be an unsprinklered interconnected floor space, consisting of the cafeteria and the floor next above it. The cafeteria is separated from the remainder of the storey by a fire separation. The Respondent further submitted that at the time this may have been viewed as one storey and one fire compartment on different levels, which would be consistent with the buildings split level design.

2. **Commission Ruling:**

It is the decision of the Building Code Commission that not sprinklering the interconnected floor space designated as a student lounge does not provide sufficiency of compliance with Sentence 3.2.8.2.(6) of the Building Code.

3. **Reasons:**

vi. No proposed alternatives other than a 1 hour vertical fire separation were provided to allow the Commission to consider sufficiency of compliance.
vii. The construction does create an interconnected floor space and the provisions of Sentence 3.2.8.2.(6) of the Building Code apply.

Dated at Toronto, this 1st day, in the month of August, in the year 1996, for application number 1996-40.

IN THE MATTER OF Subsection 24(1) of the *Building Code Act, 1992.*

AND IN THE MATTER OF Sentences 3.4.2.1.(1), 3.4.4.1.(1), 3.4.4.2.(2) & 3.5.3.1.(1) and Clause 3.4.4.2.(2)(b) of the Revised Regulation of Ontario 1990, Regulation 61, as amended by O.Regs. 400/91, 158/93, 160/93, 383/94 and 20/95 (the "Building Code").

AND IN THE MATTER OF an application by Mr. Gary McCluskie, Architect, A.J. Diamond, Donald Schmitt and Company, Architects, Toronto for the resolution of a dispute with Mr. Palle D. Hansen, Chief Building Official, The Corporation of the City of York, concerning three issues: i) Interpretation of the technical requirements of Sentences 3.4.2.1.(1), 3.4.4.1.(1), and 3.4.4.2.(2). At issue is the proposed use of Stair No. 1 as an exit through a lobby, to provide one of the required exits to serve the basement and second floor, in addition to the ground floor. ii) Sufficiency of compliance with the technical requirements of Clause 3.4.4.2.(2)(b). At issue is the maximum path of travel of 16.45 m from the entry into the lobby at the second floor level to the exterior exit door at ground level. iii) Sufficiency of compliance with the technical requirements of Sentence 3.5.3.1.(1) and Table 3.5.3.A. At issue is the use of unlabelled elevator doors on the ground floor and second floor entrances into the elevator car.

RULING

1. **The Applicant**

   Mr. Gary McCluskie, Architect, A.J. Diamond, Donald Schmitt and Company, Architects, is an applicant for a permit under the Building Code Act, 1992 to construct a new two storey library building at the corner of Oakwood Avenue and Holland Park Avenue, City of York, Ontario.

2. **Description of Constrution**

The proposed building is a new library (Group A, Division 2), for the City of York. The building is two storeys is building height with one basement. The building area is approximately 505 m?.

The ground floor and second floor accommodate the library collection and library functions. The basement has a multipurpose room, two small classrooms, public washrooms and service spaces. The multipurpose room and classrooms may be used as part of the library programming or for community functions and activities. One passenger elevator serves the basement, ground and second floors.

Construction is proposed to be of noncombustible construction and the building will be protected by a supervised automatic sprinkler system and a fire alarm system. The fire alarm system is designed to transmit a signal to the fire department on activation of an alarm initiating device.

The ground floor (first storey) and second floor are an interconnected floor space conforming to Sentence 3.2.8.2.(6) of the Building Code.

The lobby at the front of the building adjacent to the main entrance incorporates Stair No. 1 which provides one of the required exits from each of the second floor, the ground floor and the basement.

The path of travel to the outdoors from the basement is approximately 11 m. The path of travel from the entry into the lobby at the second floor level down Stair No. 1 to the outdoors at the ground floor level is approximately 16.75 m.

The elevator doors opening into the ground floor and second floors are within an interconnected floor space conforming to Sentence 3.2.8.2.(6) of the Building Code. The elevator doors on the ground floor and second floor are proposed to contain wired glass in the steel elevator door frame.

3. **Dispute**

The subject dispute involves the following three issues:

i. Interpretation of the technical requirements of Sentences 3.4.2.1.(1), 3.4.4.1.(1), and 3.4.4.2.(2) of the Building Code. At issue is the proposed use of Stair No. 1 as an exit through a lobby, to provide one of the required exits to serve the basement and second floor, in addition to the ground floor.

ii. Sufficiency of compliance with the technical requirements of Clause 3.4.4.2.(2)(b) of the Building Code. At issue is the maximum path of travel of 16.45 m from the entry into the lobby at the second floor level to the exterior exit door at ground level.

iii. Sufficiency of compliance with the technical requirements of Sentence 3.5.3.1.(1) and Table 3.5.3.A. of the Building Code. At issue is the use of unlabelled elevator doors on the ground floor and second floor entrances into the elevator car.

4. **Provision of the Building Code**

Sentence 3.4.2.1.(1) Minimum Number of Exits

1. Except as provided in Sentences (2) to (4), and (6), every floor area as regulated in Article 3.4.1.1. shall be served by not less than 2 exits.

Sentence 3.4.4.1.(1) Fire-Resistance Rating of Exit Separations

2. Except as provided in Article 3.4.4.3. and Sentences (2), 3.3.5.5.(3) and 3.4.4.2.(2), every exit shall be separated from each adjacent floor area by a fire separation having a fire resistance rating not less than that required for the floor assembly above the floor area and, where there is no floor assembly above, not less than that required by Subsection 3.2.2. for the floor assembly below, but in no case shall the fire resistance rating be less than 45 min.

Sentence 3.4.4.2.(2) Exits Through Lobbies

ii. Not more than 1 exit from a floor area is permitted to lead through a lobby provided

a. the lobby floor is not more than 4.5 m (14 ft 9 in) above grade,
b. the path of travel through the lobby to the outdoors is not more than 15 m (49 ft 3 in),
c. the adjacent rooms or premises having direct access to the lobby do not contain a Group C or F occupancy,
d. except as required in Clause (g), the lobby is not located within an interconnected floor space other than as described in Sentence 3.2.8.2.(6),
e. the lobby conforms to the requirements for exits, except that

i. rooms other than service rooms and storage rooms may open onto the lobby,

ii. the fire separation between the lobby and a room used for the sole purpose of control and supervision of the building need not have a fire resistance rating, and

iii. the fire separation between the lobby and adjacent occupancies that are permitted to open onto the lobby need not have a fire- resistance rating when the lobby and adjacent occupancies are sprinklered,

f. the fire separation required in Sentence 3.4.4.1.(1) shall be maintained between the exit and the lobby, and

g. that if the exit serves a hotel, the lobby is not located within an interconnected floor space.

Sentence 3.5.3.1.(1) Fire Separations for Vertical Service Spaces

8. Except as provided in Sentence (2), every vertical service space shall be separated from each adjacent floor area by a fire separation having fire-resistance rating conforming to Table 3.5.3.A. for the fire-resistance rating required for the floor assembly above, conforming to that required by Subsection 3.2.2. for the floor assembly below.

5. **Applicant's Position**

Issue 1: Stair No. 1, Exit Through a Lobby

The Applicant submitted that the exit through the lobby complies with the technical requirements of Sentences 3.4.4.1.(1) and 3.4.4.2.(2) as an exit through a lobby serving the basement, ground floor and second floors of the Oakwood Library.

Stair No. 2 is a conventional enclosed exit stair, separated from the remainder of the building by a 45 min fire separation, discharging directly to the outdoors at the ground level at the rear of the building.

Stair No.1 is contained within a lobby which provides the second exit from each storey (basement, ground and second floors) and discharges to the outdoors at the ground level at the front of the building adjacent to the main entrance. The Applicant submitted that the requirements of Sentence 3.4.4.2.(2) of the Building Code have been met.

The Applicant submitted that the lobby is used solely for access to, and egress from, the basement, ground and second floors. There is no furniture or equipment located in the lobby, and no fire load.

Issue 2: Path of Travel Through the Lobby

The Applicant submitted that the path of travel through the lobby provides sufficiency of compliance with the technical requirements of Clause 3.4.4.2.(2)(b) of the Building Code based on the design of a shallower sloped, safer stair.

The Applicant submitted the following to support his position:

The path of travel through the lobby from the second floor to the outdoors at the ground floor level is approximately 16.45 m, which exceeds the 15 m permitted by Clause 3.4.4.2.92)(b) of the Building Code.

The 15 m limit on the path of travel through a lobby is intended to limit the exposure of occupants to hazards in an occupancy adjacent to the lobby under emergency evacuation conditions. Stair No. 1 has a rise of 158 mm and a run of 250 mm exclusive of nosing. These dimensions provide a shallower sloped stair than that based on the maximum riser height and the minimum run permitted by the Building Code. A stair design for Stair No. 1 based on the minimum run of 230 mm and maximum rise of 200 mm permitted by Sentences 3.4.6.7.(1) and (2) would result in reduction of the maximum path of travel through the lobby to the outdoors at ground level that does not exceed 15 m in compliance with Clause 3.4.4.2.(2)(b) of the Building Code.

However, research has shown that stairs with a shallow slope provide a safer path of travel. This research has led to changes in the 1995 National BuildIng Code of Canada to require shallower maximum slopes for exit stairs (i.e. minimum run of 280 mm and maximum rise of 180 mm).

Stair No. 1 is the main means for the public to access the basement and the second floor of the library. A shallower slope of stair with lower risers and wider treads are proposed to provide a comfortable stair for use by the public in this relaxed library setting. A stair with a shallower slope provides a safer, more efficient stair for normal occupant use and for emergency evacuation.

The increase in path of travel through the lobby of 1.45 m (over the 15 m permitted by Clause 3.4.4.2.(2)(b)) represents an insignificant increase in the time required for occupant evacuation (approximately 1 second), which will be offset by an increase in safety for users of the Stair No. 1.

Issue 3: Wired Glass in Nonlabelled Doors

The Applicant submitted that the use of Wired Glass in nonlabelled elevator doors at the ground and second floor level provides sufficiency of compliance with the technical requirements of Clause 3.2.2.21.(2)(a) and Sentence 3.2.8.2.(6) of the Building Code and that the elevator shaft in this building is not considered as a vertical service space.

The Applicant submitted that the elevator doors on the ground floor ad second floor will contain wired glass in a steel elevator door. Each pane of wired glass will not exceed 0.84 m? in accordance with the area limitations in Clause 3.1.8.14.(2) of the Building Code. The elevator manufacturers who have submitted bids for the project, have advised the architects that they cannot provide labelled elevator doors containing wired glass as they have not tested such doors.

The Applicant submitted that the elevator doors opening into the ground floor and second floors are within an interconnected floor space conforming to Sentence 3.2.8.2.(6) of the Building Code. The Applicant proposed to consider the elevator shaft below the ground floor slab, as part of the ground floor fire compartment, separated from the remainder of the basement by a 45 min fire separation - the same as is required between the basement and the ground floor. As the ground floor and the second floor are interconnected, they can be considered the same fire compartment, including the elevator shaft. The elevator shaft, in this approach, is not considered as a vertical space.

The Applicant further submitted that in other situations where supervision and security concerns, such as rapid transit stations, elevators are permitted to be enclosed by either 1 h fire separations, or wired glass assemblies.

6. **Chief Building Official's Position**

The Respondent submitted the following information to support the municipalities position:

Reference to Sentence 3.4.2.1.(1)

Since the occupant load of each of the floor areas exceeds 60 persons, two exits are required to serve each floor area. Exceptions referenced in the Sentence do not apply for this project.

Reference to Sentence 3.4.4.2.(1)

The basic principle of this Sentence is that any required exit serving a floor area, other than the first storey, must not lead through a lobby. An exit means that part of a means of egress that leads from the floor area it serves, to a separate building, an open public thoroughfare, or an exterior open space protected from fire exposure from the building and having access to an open public thoroughfare.

This Sentence also provides a direct indication that a "lobby" is considered as part of the first floor area since an exit serving the first floor is permitted to lead through a lobby. Lobby has the meaning of "entrance hall" or " passageway" which serves to provide a common area for access to or from a building. It is not the intent of the Code to treat an exit stair, (stairway), which extends through all floor levels of the building as a "lobby".

Reference to Sentence 3.4.4.2.(2)

This Sentence provides the exception to the preceding Sentence to permit one exit from a floor level, in addition to an exit serving the first storey, to lead through a lobby. The Clauses contained in the Sentence provide specific requirements that the lobby must meet in order to maintain the integrity of any exit leading through it. It is clear that the "exit" and the "lobby" are separate entities, each with specific requirements related to their purpose.

Reference to Clause 3.4.4.2.(2)(a)

The floor of the lobby is permitted to be a maximum of 4.5 m above grade. This clause provides for the relationship between the floor level at which point one normally leaves the floor area to gain the protection of an exit enclosure, and the level outside of the building presumed to be safe and clear of the building. This Clause also clearly states that this exception does not apply to below grade levels.

Reference to Clause 3.4.4.2.(2)(b)

The path of travel for a person exiting the building is limited to 15 m. This Clause provides for an acceptable distance in which a person exiting a floor area is doing so through a lobby which provides a reduced level of protection from that for the exit enclosure.

Reference to Clause 3.4.4.2.(2)(d)

In the case of a library use building, a lobby through which an exit leads is not permitted to be located within an interconnected floor space except where the interconnected floor space meets the limitations of Sentence 3.2.8.2.(6). Clause (a) of Sentence 3.2.8.2.(6) provides specific requirements which limit the interconnected floor space to not more than two storeys, one of which must consist of the first storey. It is clear that the interconnection of floor levels is not to include all the levels of the subject building. The proposed lobby concept would not comply with the interconnected floor space requirements.

Reference to Clause 3.4.4.2.(2)(e)

This Clause requires that the lobby provide a level of design conforming to that of an exit with exceptions to permit specific low hazard ancillary uses within the lobby as long as the lobby and adjacent ancillary uses are sprinklered. This Clause further supports the contention that a lobby is not an exit, but can be used to provide for the continuation of an exit under very specific and restrictive conditions.

National Building Code 1995 - Appendix A-3.4.4.2.(2)(e)

Requirements for Lobby. If an exit is permitted to lead through a lobby, the lobby must provide a level of protection approaching that of the exit. As well as meeting the width and height requirements for exits, the lobby must be separated from the remainder of the building by a fire separation having a fire resistance rating at least equal to that required for the exit, unless one of the exceptions in this Clause applied.

Reference to Clause 3.4.4.2.(2)(f)

This Clause serves to maintain the minimum standards for the fire protection of exits as contained in Sentence 3.4.4.1.(1). This Clause also provides for a clear distinction between "exit" and a "lobby".

Exit Requirements - Reference to Article 3.4.4.1.

This Article provides basic requirements for fire resistance ratings for exit separations. This Article also applies to all exits. Sentence (1) of the Article provides an exception for the requirement for a fire separation having a fire resistance rating between the lobby serving an exit, ("a lobby is to conform to the requirements for exits") and each adjacent floor area. If read

correctly, this Sentence permits the relaxation of the requirements for fire resistance ratings for fire separations between the lobby, which serves as an exit, and specifically permitted ancillary occupancies, (rooms used for the sole purpose of control and supervision of the building). The last portion of the Sentence clearly indicates the need to maintain a minimum fire resistance rating between the exit and the lobby as further referenced in Clause 3.4.4.2.(2)(f). The Building Code draws a clear distinction between a "lobby" and an "exit", with a higher level of fire protection being required to ensure the integrity of the exit facility.

National Building Code - Guidelines for the Application of Part 3 - Protection of Exit Facilities

The fundamental need to protect an exit facility is to ensure that it will not be invaded by fire products of combustion during the time that it is being used for the excavation of the building occupants and its availability for fire fighters attempting to suppress the fire and assisting occupants to evacuate the building. As a result of a minimum standard established for the protection of exits, it is not acceptable to have an exit stair open to adjacent storeys.

Elevator Shaft

Sentence 3.2.8.1.(2) of the Building Code clearly identifies a specific concern regarding penetrations of floor assemblies by exits and vertical service spaces.

Vertical service spaces are described as shafts for mechanical and electrical services that pass from floor to floor including hoistways for elevators. The elevator shaft is required to be protected from the effects of a fire in the adjacent library stacks floor areas, which could potentially contribute a considerable fire load. Likewise, the adjacent floor areas are to be protected from a fire in the service space. Sentence 3.5.3.1.(1) and Table 3.5.3.A. specifically require a minimum 45 minute fire resistance rated elevator shaft even though the fire resistance rating of the floor assembly which it penetrates is zero. The Building Code, under Subsection 3.1.8. requires all fire separations to be continuous and any openings within the fire separation are to provide a proven level of protection of the opening in order to maintain the continuity. The use of unlabelled elevator doors serving the first and second storeys is not consistent with the Code requirements.

7. **Commission Ruling:**

It is the decision of the Building Code Commission that:

i. The current design of the proposed exit Stair No. 1 does not comply with the requirements of Sentences 3.4.2.1.(1), 3.4.4.1.(1), and 3.4.4.2.(2) of the Building Code without the required fire separations.

ii. An exit enclosure for Stair No. 1 conforming to Sentence 3.1.8.14.(2) of the Building Code provides sufficiency of compliance with the required 45 minute fire separation.

iii. The use of unlabelled elevator doors containing wired glazing on the ground floor and second floor located within the interconnected floor space provides sufficiency of compliance with Sentence 3.5.3.1.(1) and Table 3.5.3.A. of the Building Code.

8. **Reasons:**

i. The argument that a lobby is part of the exit which leads into it, and as such, need not be separated from the exit shaft is in the opinion of the Building Code Commission not in accordance with the required fire resistance rating of the exit enclosure that must be provided between the lobby and the exit shaft.

ii. The principal of protection from fire exposure when entering an exit stair is clearly enunciated in Sentence 3.4.4.1.(1) of the Building Code.

iii. It is the opinion of the Building Code Commission that the use of wired glazing other than the area limitations in Table 3.1.8.B. of the Building Code provided an acceptable level of safety since travel distance from any point on the second floor and basement to the exterior is less than 45 m.

Dated at Toronto, this 23rd day, in the month of August, in the year 1996, for application number 1996-39.

RULING

1. **The Applicant**

   Mr. Patrick Chan, President, Kingsberg Far East Ltd., Markham is the holder of a permit under the Building Code Act, 1992 to construct a two storey addition to an existing two storey commercial building that will contain 114 market style shops on the ground floor at the New Century Plaza, 398 Ferrier Street, Ontario.

2. **Description of Constrution**

   The subject building is a 4,574 m² two storey addition to an existing 1,630 m² two storey Group A, Division 2 building. The addition consists of a ground floor "market style" retail occupancy (Group E) and two levels of Group F, Division 3 open-air parking with the uppermost level being on the roof of the building.

   A two hour fire separation is proposed between the existing two storey building and the proposed addition. Egress for the existing two storey building will be completely independent of the new addition.

The proposed two storey addition will be fully sprinklered and the expanded building will have one fire alarm system.

The fire department access will be provided on all four sides of the building. Access route required by the Building Code will be provided only to the principal building entrance since the building is sprinklered.

Twelve exterior exit doors will be provided at ground level, each having a width of 915 mm. This amounts to a aggregate exit width of 10,980 mm providing exit capacity for 1,800 persons, or 2.3 times the Building Code required exit capacity.

The proposed design also includes the following:

i. The retail shops will be accessible from the circulation aisles, i.e., no rear service corridors.
ii. Shops will not exceed 200 m? or a depth of 25 m and therefore require only one egress doorway as provided in Sentence 3.3.1.5.(1) of the Building Code.
iii. Travel distance from anywhere on the main floor to at least one exit door will not exceed 45 m as required in Sentence 3.4.2.5.(1)(b) of the Building Code.
iv. At the point where a retail shop opens into a circulation aisle, it will be possible to travel in opposite directions to separate exits as required in Sentence 3.3.1.9.(9) of the Building Code.
v. The demising wall between retail shops will be a (i.e., unrated 13 mm gypsum board on both sides of metal studs, joints filled with tape and compound) fire separation continuous from the concrete floor slab to underside of the ceiling.
vi. Circulation aisles will range in unobstructed width from 3.96 m (13 ft) to 4.88 m (16 ft) wide.
vii. Circulation aisles will not be fire separated from the retail shops. Instead, security closures separating the shops from circulation aisles will permit each shop to be visible. Sliding or rolling security screen permitted by Sentence 3.3.1.11.(3) of the Building Code will be provided in lieu of a swinging egress door.
viii. Smoke detection, connected to the fire alarm system, will be spaced not more than 10 m apart in the circulation aisles.
ix. Circulation aisles will be clearly identified as access to exit routes by the use of directional exit signs at each change in direction and by emergency lighting providing at

least a average illumination of 10 lx floor level as required in Articles 3.4.5.1. ad 3.2.7.3. of the Building Code.

x. Building Security and operation for all occupants is provided by building owners so that all floor areas are controlled as if they are occupied by only one tenant.

3. **Dispute**

The dispute between the Applicant and Respondent concerns sufficiency of compliance with Sentence 3.3.1.1.(2) and Clause 3.3.1.4.(1)(c) the Building Code. At issue is the proposed ground floor market style retail layout with no fire separation between units nor between units and circulation routes where the corridor widths are 5 m or less in width.

4. **Provision of the Building Code**

Article 1.1.3.2. Definition of Suite

Suite means a single room or series of rooms of complementary use, operated under single tenancy, and includes dwelling units, individual guest rooms in motels, hotels, boarding houses, rooming houses and dormitories as well as individual stores and individual or complementary rooms for business and personal services occupancies.

Sentence 3.3.1.1.(2) Separations of Suites

1. Except as permitted by Sentence (2), each suite in other than business and personal services by a fire separation having a fire-resistance rating of not less than 1 h, except that a fire resistance rating of not less than 45 min is permitted where the fire-resistance rating of the floor assembly is not required in Subsection 3.2.2. to be more than 45 min. (See also Subsection 3.3.3. for institutional occupancies, Article 3.3.4.2. for residential occupancies and Article 3.1.8.7. for fire dampers.)
2. In sprinklered buildings, suites of business and personal services occupancy and mercantile occupancy that are served by public corridors conforming with Clause 3.3.1.4.(1)(c) are not required to be separated from each other by fire separations.

Clause 3.3.1.4.(1)(c) Public Corridor Separations

3. Except as otherwise required in this Part, public corridors shall be separated from the remainder of the building by a fire separation having a fire-resistance rating of not less than 1 hour except that

a. the fire-resistance rating need not be more than 45 min when the fire resistance rating of the floor assembly is not required to be more than 45 min,
b. no fire-resistance rating is required when the floor area is sprinklered and the corridor does not serve an institutional occupancy or a residential occupancy,
c. no fire separation is required in a sprinklered floor area where,
    i. the corridor is more than 5 m in unobstructed width, and
    ii. the corridor does not serve an institutional occupancy or a residential occupancy,
d. a floor assembly above a crawl space that is not considered a basement in Sentence 3.2.2.5.(2) is not required to be a fire separation, and
e. no fire separation is required in a sprinklered floor area where an occupancy in the corridor conforms to the requirements of Sentence 3.3.1.9.(6).

5. **Applicant's Position**

The Applicant proposed that the main floor market style layout be considered equivalent to a department store or exhibition hall rather than each retail shop being a separate suite.

The Applicant submitted that increasing the proposed circulation isles (that range from 3.96 to 4.88 m) to more than 5 m would not be economically viable and constructing unrated fire separations between the shops and circulation isles would defeat the market style concept that is proposed for the ground floor.

The Building Code requires a 1 hour fire separation between shops because the circulation aisles will not exceed 5 m in unobstructed width. No fire separation is required by the Code where the corridor exceeds 5 m in width. A fire separation, continuous from the floor slab to underside of the ceiling, consisting of a layer of unrated 13 mm gypsum board on both sides of metal studs is proposed in this case. The joints will be filled with tape and compound.

The Applicant submitted that it is reasonable to consider the proposed market style retail floor similar to a department store or other indoor market style layout (i.e. St. Lawrence Market) because the proposed retail shops can not operate independently in terms of building systems and security as could be the case in conventional multiple suite floor areas such as those found in office and residential buildings.

The Applicant submitted that each retail shop is a condominium and therefore separately owned, however, the operations and security for the retail floor area will be similar to a department store. The circulation aisles will be more clearly defined in this case by the circulation aisles compared

to a department store layout which will reduce the likelihood that access to exit routes could become partially obstructed. The market style layout will in some ways be better than a department store, merchandising layouts and circulation aisles can not be changed or obstructed.

Furthermore, the Applicant submitted that the proposed conditions provide sufficiency of compliance with the Building Code for the suite and corridor separation provided:

. proposed aggregate exit width of 10,890 mm for ground floor, provides 2.3 times the Building Code required aggregate exit width of 4,776 mm;

i. smoke detection, connected to the fire alarm system will be spaces not more that 10 m apart in the circulation isles;

ii. several choices in direction of exit travel in parts of the circulation route compared to conventional shopping mall where there may only be a choice of two directions of exit travel; and,

iii. a signed fire truck route be provided on all four sides of the expanded building.

6. **Chief Building Official's Position**

The Respondent submitted that the ground floor retail area will contain a undetermined number of Group E condominium units. In the opinion of the Respondent, each condominium unit is by definition a suite and must therefore conform to all applicable requirements of the Building Code.

The Respondent submitted that Sentence 3.3.1.3.(8) requires each suite to have an exterior exit door or a doorway into a public corridor or to an exterior passageway. Therefore, the aisles between suites on the subject floor area must be designed as public corridors conforming to the requirements of Section 3.3 of the Building Code.

The Respondent submitted that in sprinklered buildings where Group E suites are served by a public corridor greater than 5.0 m in width, no fire separation is required between the suites (Sentence 3.3.1.1.(2)) and furthermore, no fire separation is required between the suite and the corridor (Clause 3.3.1.4.(1)(b)).

Furthermore, the Respondent submitted that the public corridors proposed by the Applicant range in width from 4.0 m to 4.8 m. Therefore, the Building Code requires suites to be separated from each other by 1 hour fire separations (Sentence 3.3.1.1.(1)) and be separated from the public corridors by at least a nonrated fire separation (Clause 3.3.1.4.(1)(b)).

The Respondent submitted that the Applicant is proposing to eliminate the fire separation between suites and to eliminate the fire separation between the suites and the public corridor. Therefore, the proposal does not comply with the Building Code.

7. **Commission Ruling:**

It is the decision of the Building Code Commission that not providing fire separations between units, and units and circulation routes on the ground floor of a market style retail mall where the corridor widths are less than 5 m provides sufficiency of compliance with Sentence 3.3.1.1.(2) and Clause 3.3.1.4.(1)(c) of the Building Code provided:

. The travel distance from any point in a suite to an exit does not exceed 45 metres.

i. The common areas operate as a market style retail space operated by a condominium management.

ii. The aisle location, spacing and exit widths that have been provided are maintained.

iii. Security closures separating units from the circulation corridors permit the interior of the stores to be visible.

8. **Reasons:**

. The exit capacity has been designed to accommodate 2.3 times the Building Code required width.

i. The aisles or access to exits provide several choices in direction of exit travel in parts of the circulation route compared with conventional shopping malls.

ii. Smoke detectors connected to the fire alarm system spaced not more than 10 m apart are provided in the corridors.

iii. Fire access routes are provided on all four sides of the building.

Dated at Toronto, this 23rd day, in the month of August, in the year 1996, for application number 1996-38.

RULING

1. **The Applicant**

   Ms. Elizabeth Sawicki, NHD Developments Limited is the holder of a permit under the Building Code Act, 1992 to construct a one storey Medium Hazard Industrial Occupancy (i.e. Group F, Division 2) at 336 Courtland Avenue, Vaughan, Ontario.

2. **Description of Constrution**

   The subject building has a building area of 19,500 m² comprising a single 17,900 m² storey warehouse and a 1,600 m² office component having a 1,250 m² mezzanine.

   The building is designed in accordance to Article 3.2.2.55. of the Building Code which requires noncombustible construction, an automatic sprinkler system, the mezzanine floor to have 1.5 hour fire resistance rating, and the roof to have a 1.5 hour fire resistance rating.

   The exterior walls of the warehouse are constructed of precast panels, each having a inherent 2 hour fire resistance rating.

The north wall of the building has a length of 155.75 m and a height of 9.25 m. The limiting distance, measured to the property line is 8 m. The percentage of unprotected openings is 22.4.

Structural clips at the top of the wall provide lateral support to the exterior wall. The protection of the lateral support clips are the subject of the dispute.

3. **Dispute**

The dispute between the Applicant and Respondent concerns an interpretation of the technical requirements of Clause 3.2.3.7.(2)(b) of the Building Code. At issue is whether the lateral support clips and the supports of lateral clips for the precast concrete wall are required to have a 2 hour fire resistance rating.

4. **Provision of the Building Code**

Clause 3.2.3.7.(2)(b) Construction of Exposing Building Face

2. Except as permitted in Article 3.2.3.9., where a limiting distance shown in Table 3.2.3.B. for a Group E, or Group F, Division 1 or 2 occupancy classification is such as to permit an exposing building face to have unprotected openings of

(b) more than 10 per cent but not more than 25 per cent of the exposing building face shall have a fire resistance rating of not less than 2 h, and be clad with noncombustible cladding.

5. **Applicant's Position**

The Applicant submitted that the lateral supports for the precast wall assemblies at 336 Courtland Avenue simply provides lateral stability to the precast wall. The Applicant submitted the following concerning the fire rating of the lateral supports and their supporting structure:

ii. In a sprinklered building, the Building Code waives the requirement for the fire resistance rating of the roof. The fire resistance rating of the structure providing the lateral support to a precast wall structure is not referenced in the Building Code as requiring a rating.

The lateral connectors and supports are located on the roof. The precast wall is self supporting in that it can bear its own weight. In the event of a fire, the sprinkler system will activate and cool the structure and lateral supports for the duration of the fire.

As part of the acceptance testing for sprinklers, the sprinklers must reduce the average ceiling temperature to less than 500 degrees F after 5 minutes of activation.

The yield temperature of steel is significantly reduced when exposed to temperatures above 1100 degrees F. Since this temperature will not fail while the sprinkler system remains in operation.

Since the Building Code acknowledges that the roof of a sprinklered building will not collapse, all structural elements are protected, especially those above the sprinklers. The need to rate the lateral connectors and the supporting structure is not required.

iii. The lateral connectors are located on the roof of the building, outside of the building and will not be exposed to a fire occurring within the building.

The need to rate the lateral connectors, since they are on the outside of the building is not required by the Building Code.

iv. Should the temperature at the ceiling be elevated to such a level that the lateral connectors begin to fail, the fire has grown to such a size that it overtaxes the sprinkler system.

The sprinkler system in the subject building has been designed based on the commodities stored within the facility and is anticipated to contain, control or extinguish a fire. The Building Code expects the sprinkler system designed to NFPA 13 to achieve the above goal.

To anticipate failure of the sprinkler system is not a reasonable expectation. If the sprinklers were not to achieve their goals, the structural steel in the building would be exposed to temperatures resulting in structural failure. Since the structure has failed, the heat energy will no longer be only radiating horizontally to the adjacent buildings, but also will radiate upwards. The impact on the adjacent properties will reduce significantly. In radiating upwards, the concern to the adjacent property is proportionately reduced.

The Applicant summarized the above by submitting that the need to protect the lateral supports of the exterior wall is neither a Building Code requirement nor is it necessary in a fully sprinklered building.

2. **Chief Building Official's Position**

The Respondent submitted that the north elevation of the subject building requires a 2 hour fire resistance rating in accordance with Clause 3.2.3.7.(2)(b) of the Building Code. The north elevation wall is constructed of precast concrete panels laterally supported by a structural angle clip at the top of the wall which is supported by the structural frame of the building. As a result the angle clip and supporting structure is required to be rated to a 2 hour fire resistance rating.

The Respondent submitted that the Building Action Newsletter of April 1994 produced by the Housing Development and Buildings Branch, Ministry of Municipal Affairs and Housing states that "if the exterior walls are required to have a fire resistance rating (as for spatial separation) the bracing angles must be protected for the same fire resistance rating as the walls.

The Respondent also submitted that a letter from the Code Development and Technical Training Section of the Housing Development and Buildings Branch, Ministry of Municipal Affairs and Housing to Mr. David Hine of Morrison Hershfield, states that "where the roof provides lateral support for an exterior wall required by Article 3.2.3.7. to have a fire resistance rating, Article 3.2.3.7. does not require the roof to have a fire resistance rating." Clearly, this interpretation does not address the issue of rating the supporting structural steel columns and angle clips.

The Respondent stated that the structural frame (i.e. the columns supporting the portion of the roof providing support for the lateral clips) must have a 2 hour fire resistance rating equivalent to the subject exposing building face.

3. **Commission Ruling:**

It is the decision of the Building Code Commission that lateral support clips and the supports of the lateral clips required for the wall having a 2 hour fire resistance rating for exposure protection does not require a 2 hour fire resistance rating in accordance with Clause 3.2.3.7.(2)(b) of the Building Code.

4. **Reasons:**

ii. It is the opinion of the Building Code Commission that the Building Code does not have any provision requiring lateral support connectors to be rated when a wall is required to have a fire resistance rating for spatial separation purposes.

iii. The building is equipped with a supervised sprinkler system and the fire resistance rating of the roof assembly is waived.

iv. In addition the openings in the exterior wall are less than the maximum permitted.

Dated at Toronto, this 11th day, in the month of September, in the year 1996, for application number 1996-37.

BCC Ruling No. 96-33-516

BUILDING CODE COMMISSION DECISION ON B.C.C. #96-33-516

For the Respondent

RULING

1. **The Applicant**

   Ms. Sandra Gunn, 1034177 Ontario Ltd. is the holder of a permit under the Building Code Act, 1992 to construct a single family dwelling (i.e. house) at 7930 Kipling Avenue, Woodbridge, Ontario.

2. **Description of Constrution**

   The subject building is a three storey house with an attached garage.

   Upon completion of the house, the Applicant applied for and received a zoning by-law amendment to permit the use of an office on the first floor. No additional construction was proposed for the office use.

   The Respondent issued a deficiency letter to the Applicant requiring the following remedial work be under taken:

i. Existing window openings in the south elevation of the building must be closed in with similar face brick.

ii. Existing exits from the basement are to be protected by a 30 minute fire separation. (Existing exit into garage will be allowed if a clear path to the main door through the garage is maintained.)

3. **Dispute**

The dispute between the Applicant and the Respondent concerns sufficiency of compliance with Sentence 9.9.4.2.(1) and Article 9.10.14.11. of the Building Code. At issue is whether the stairway from the basement need be constructed as an exit and if the existing window openings in the south exposing building face must be closed in with similar face brick.

4. **Provision of the Building Code**

`Sentence 9.9.4.2.(1) Fire Separation for Exits`

1. Except as provided in Sentence (5) and Article 9.9.8.5., every exit other than an exit doorway, shall be separated from each adjacent floor area or from another exit by a fire separation having a fire-resistance rating not less than that required for the floor assembly above the floor area. (See Article 9.10.9.10.)

Article 9.10.14.11. Construction of Exposing Building Face

Except as permitted in Articles 9.10.14.12. to 9.10.14.16., each exposing building face and any exterior wall located above an exposing building face that encloses an attic or roof space shall be constructed in conformance with Table 9.10.14.B. and Subsection 9.10.8.

Table 9.10.14.B.
Forming Part of Article 9.10.14.11

Minimum Construction Requirements for Exposing Building Faces				
Occupancy Classification of Building	Maximum Precentage of Uprotected Openings Premitted	Minimum Required Fire-Resistance Rating	Type of Construction Required	Type of Cladding Required
Residental, business and	Not more than 10	1h	Noncombustible	Noncombustible

personal services, and low hazard industrial	More than 10 but not more than 25	1h	Combustible or noncombustible	Noncombustible
	More than 25 but not more than 100	45min	Combustible or noncombustible	Combustible or Noncombustible
Mercantile and medium hazard industrial	Not more than 10	2h	Noncombustible	Noncombustible
	More than 10 but not more than 25	2h	Combustible or Noncombustible	Noncombustible
	More than 25 but not more than 100	1h	Combustible or Noncombustible	Combustible or Noncombustible
Column 1	Column 2	Column 3	Column 4	Column5

5. **Applicant's Position**

The Applicant submitted that when the first building permit was issued, it was for residential use and the amount of windows on the south side of the building was not a problem.

The Applicant submitted that since the zoning by-law was amended to a allow the operation of a business in 40% of the building, the windows in the residential area must be enclosed. There is only one 5' x 6' window in the commercial floor on the south side of the building. All other windows are for residential use. The Applicant submitted that the windows should be allowed for light and ventilation purposes.

The Applicant submitted that there are two stair ways in the basement, one in the front and one in the back. The back stair way is already enclosed so the front exit is the one in question. The Applicant proposed to install a fire rated door at the bottom of the front stair case and drywall both stair cases on the underside with two sheets of 5/8" fire rated drywall which should provide a 2 hour fire resistance rating.

The Applicant submitted that the rezoning By-law and the Site Plan Agreement were finalized after the entire building was fully constructed.

In summary the Applicant submitted that the professional office that is set up in their household is by appointment only. There are no line ups and it is not a walk in retail outlet. The office area in the home is very minimal compared to the residential occupancy. With all the advertising in

the media promoting working at home, the items that are being disputed should be of minor concern. There are many households operating businesses out of their own homes which permit small businesses to survive.

6. **Chief Building Officials Position**

The Respondent submitted that a building permit was issued to construct a single family dwelling on October 1, 1993. On November 28, 1994 a letter of credit release inspection was conducted by the area building inspector which revealed that the first floor was being used as an office. On August 28, 1995 a permit application was submitted by the owner to allow the office in the first floor. No construction was proposed. On November 7, 1995 a deficiency letter was issued to the owner requiring certain upgrades to the building to allow the use of an office on the first floor.

The Respondent submitted that a 30 minute fire separation is required around the easterly exit stair leading directly to the outdoors. Also, the existing openings in the south elevation must be closed to have a 1 hour fire resistance rating and be constructed of noncombustible construction and clad with noncombustible cladding in accordance with Table 9.10.14.B. of the Building Code.

The Respondent submitted that since this is an existing building constructed of combustible construction it would be impractical to re-construct the exterior wall with noncombustible materials. Therefore, it was decided that since this wall was clad with 4" face brick it would be allowed to be of combustible construction provided all existing openings on the south wall were closed in with similar face brick.

7. **Commission Ruling:**

It is the decision of the Building Code Commission that the exits from the basement provide sufficiency of compliance with Sentence 9.9.4.2.(1) of the Building Code and it is the opinion of the Building Code Commission that the requirements of Article 9.10.14.11. to the exposing building face are not applicable.

8. **Reasons:**

. Evaluation under Part 10 of the Building Code does not require evaluation of spatial separations.

i. There are 2 non-conforming exists from the basement level, which are well separated leading through separate fire compartments on the 1st floor level to the exterior. The building is of a size where only one exit is required.

ii. The building is equipped with smoke alarms and heat detection which are monitored.

iii. The building is operated by a single tenancy.

Dated at Toronto, this 11th day, in the month of September, in the year 1996, for application number 1996-35.

APPEARANCES

Mr. Doug Clancey, Partner
Katz Webster Clancey Associates
Ottawa, Ontario
The Applicant

Mr. Chris Freeman & Mr. Neil Dillon
City of Ottawa
For the Respondent

RULING

1. **The Applicant**

   The Applicant, Mr. Doug Clancey, Partner, Katz Webster Clancey Associates, Ottawa is the holder of a permit under the Building Code Act, 1992 to convert an existing terrace into an outdoor dining area at the Chateau Laurier Hotel, 1 Rideau Street, Ottawa, Ontario.

2. **Description of Constrution**

   The Canadian Pacific Hotels and Resorts (i.e. Chateau Laurier Hotel) proposes to provide access from an existing restaurant to an open air terrace for the purposes of outside dining.

   The open air terrace is approximately one storey above ground level. The open side of the terrace is protected by an existing granite balustrade that is 39 3/4" - 40" high. The top is approximately 16" wide and openings in the guard vary from 7" to 12 1/2".

3. **Dispute**

The dispute between the Applicant and Respondent concerns sufficiency of compliance with the technical requirements of Article 3.3.1.17. of the Building Code. At issue is the height of the existing balustrade and the provision of a temporary canvas awning attached to the inner side of the openings of an existing balustrade to meet the opening requirements for guards in the Building Code.

4. **Provision of the Building Code**

Article 3.3.1.17. Guards

1. A guard not less than 1070 mm (3 ft 6 in) high shall be provided
    a. around each roof to which access is provided for other than maintenance,
    b. at openings into smoke shafts described in Subsection 3.2.6. that are less than 1070 mm (3 ft 6 in) above the floor, and
    c. at each raised floor, mezzanine, balcony, gallery and other locations where the difference in floor elevations is more than 600 mm (235/8 in).
2. The height of guards on stairs used by the public but not forming part of a required exit shall be not less than 920 mm (3 ft) measured vertically to the top of the guard from a line drawn through the outside edges of the stair nosings and shall be not less 1070 mm than (3 ft 6 in) around landings.
3. Except as provided in Sentence 3.3.2.8.(4), the size of any opening through a required guard serving a room, stairway or space to which the public is admitted or serving an exterior balcony shall be such as to prevent the passage of a spherical object having a diameter of 100 mm (4 in) in residential occupancies, day care centres, nurseries or other similar type occupancies where children may be present and 200 mm (77/8 in) in other occupancies, unless it can be shown that the location and size of openings that exceed these limits do not present a hazardous condition.

5. **Applicant's Position**

The Applicant submitted that the Chateau Laurier Hotel is a heritage structure. The owners wish to use an existing terrace as a summer dining terrace. The terrace is quite small and will accommodate approximately 30 patrons. New access doors are being provided from an existing restaurant to the terrace.

The Applicant submitted that there is an existing granite guard (i.e. balustrade) protecting the open side of the terrace. The guard is approximately 40" high and has openings as large as 12 1/2".

The Applicant proposed that in keeping with the heritage character of the hotel, the openings in the guard be covered with a temporary coloured canvas awning attached to the inner side. The awning would be removed at the end of the outdoor dining season. The terrace would not be used during other seasons and the doors to the terrace would be locked.

The Applicant submitted that the existing height of the guard is adequate given the large width of its top.

6. **Chief Building Official's Position**

The Respondent submitted that the proposed construction is regulated under Part 11 of the Building Code in accordance with Article 2.1.1.6. Article 11.1.1.3. of the Building Code states that "where an existing building is subject to material alteration...the Building Code is applicable only to those parts of the building that are subject to the material alteration...". The Respondent submitted that in this case the alterations to allow for the installation of the new doors providing access to the terrace are clearly regulated. Additionally, the proposed installation of a canvass barrier behind the existing guardrail may be considered construction and, as such, regulated by the Building Code.

The Respondent submitted that although the canvass barrier may address the issue with respect to the openings in the guard they are concerned with the temporary nature of the installation. Given the seasonal use of the terrace, each spring the Hotel would be responsible to install the canvass barrier. The Respondent submitted that except for Restricted Permits which are issued for a specified time and subject to renewal/reapplication, approvals for building permits and occupancy permits are based on permanent solutions.

The Respondent also submitted that they have reservations concerning the guard height falling 2" short of the required 42" height set out in Sentence 3.3.1.17.(1) of the Building Code. Part 11 of the Building Code does not provide a listed Compliance Alternative for these Part 3 requirements.

The Respondent submitted that they do not have the authority to approve the installation requested by the Applicant.

7. **Commission Ruling:**

It is the decision of the Building Code Commission that providing a temporary canvas applied to the inner side of the openings of an existing balustrade on an outside dinning terrace provides sufficiency of compliance with Article 3.3.1.7. of the Building Code provided that the canvas is in place when the terrace is occupied.

8. **Reasons:**
    i. Evidence provided by the applicant demonstrated structural sufficiency required by Part 4 of the Building Code.
    ii. The existing 16" guard cap provided on the balustrade which is 40" in height compensates for the 2" deficiency from the Building Code height requirement.
    iii. The small size of the terrace limits the occupant load.

RULING

1. **The Applicant**

   Mr. Jeff Kistner, Manager HVAC & Electrical, Ontario Electrical Construction Company Ltd., Toronto is the recipient of an order to comply under the Building Code Act, 1992 concerning the installation of six gas fired heating appliances installed in each of two portable classrooms at the North Preparatory School, 1100 Spadina Road, Toronto, Ontario.

2. **Description of Constrution**

   The subject buildings are two existing portable classrooms. They each have a building area of approximately 71 m² (768 ft²).

   The Applicant replaced existing electric baseboard heaters with new natural gas sealed combustion heaters.

3. **Dispute**

   The dispute between the Applicant and Respondent concerns sufficiency of compliance with the technical requirements of Article 3.9.3.7. of the Building Code. At issue is the use of gas fired sealed combustion heaters mounted within 4.2 metres of an egress doorway in a portable classroom without a 1.5 hour fire separation between the appliance and the classroom.

4. **Provision of the Building Code**

Article 3.9.3.7. Fuel-Fired Appliances

1. Except as provided in Sentence (2), where a portable classroom contains a fuel-fired appliance, the appliance shall be separated from the remainder of the classroom by a fire separation having a fire-resistance rating of not less than
    a. 1.5 h where the horizontal distance between portable classrooms is 1.5 m (4 ft 11 in) or less, and
    b. 45 min where the horizontal distance between portable classrooms is more than 1.5 m (4 ft 11 in) but less than 6 m (19 ft 4 in).
2. Where the horizontal distance between portable classrooms is 6 m (19 ft 4 in) or more, a fuel-fired appliance need not be separated from the remainder of the classroom by a fire-separation provided
    a. there is not more than 1 appliance per portable classroom, and
    b. the appliance is located not less than 4.5 m (14 ft 9 in) from an egress doorway or an exit from the portable classroom.

5. **Applicant's Position**

The Applicant submitted that a building permit was issued by the Respondent on August 15, 1995 to permit the installation of gas fired baseboard heating units in two portable classrooms at the North Preparatory School. The subject portable classrooms are approximately 10 feet apart.

The Applicant submitted that an order to comply was issued on April 19, 1996 requiring removal of the gas fired baseboard heating units by May 15, 1996.

The Applicant submitted that they wish to use gas fired sealed combustion heaters in lieu of the various types of electrical heat used in the Metro Toronto School Board portables. The features of the unit include:

- fire and gas monitor protection
- sealed combustion with no open flame to ignite a combustible gas
- regular maintenance
- dramatic saving in energy cost
- mounting will be more than 4.2 m from an exit
- maximum exit distance is 4.5 m
- certification by CSA and CGA

Also, the Applicant stated that gas detectors and smoke alarms are provided in the classroom portables.

The Applicant submitted that open flame type gas fired units are used in other school classrooms and residences where children are present and exit distances are longer and where regular maintenance is not necessarily present.

The Applicant further submitted that they realize that gas fired appliances may be used if located in closets with appropriate fire resistance ratings. However, the closet requires to much space and destroys the economics. The Applicant requested the Commission approve the use of the baseboard heaters installed in the portables at the North Preparatory School.

Alternatively, the Applicant requested the Commission permit the use of one "hi boy" unit instead of the gas baseboard units.

6. **Chief Building Official's Position**

The Respondent submitted that the Applicant has installed six fuel (gas) fired heating appliances in each of two portable classrooms in contravention of Article 3.9.3.7. of the Building Code.

The Respondent submitted that there is more than one appliance in each portable. A total of six per portable have been installed. Also, an appliance is located closer than 4.5 m from the exit doorways from the portable in each of the two units.

The Respondent further submitted that the Applicant does not wish to construct a fire separation between the appliance and the remainder of the classroom.

Also, the Respondent expressed concern that the exhaust cup (outlet) is hot and appears to be a hazard to children.

7. **Commission Ruling:**

It is the decision of the Building Code Commission that the installation of the fuel fired appliances installed in the portable classrooms does not comply with Article 3.9.3.7. of the Building Code.

8. **Reasons:**

. The distance between the portable classrooms is less than 6 m.

i. These systems have not been used extensively in portable classrooms.

ii. It is the opinion of the Building Code Commission that alternatives presented did not demonstrate sufficiency of compliance with the Building Code.

iii. It is the opinion of the Building Code Commission that this issue should be reviewed through the Building Code amendment process to consider this technology for use in portable classrooms.

RULING

1. **The Applicant**

   Mr. Peter Thompson, Director of Facilities Management, Ottawa Civic Hospital is the holder of a permit under the Building Code Act, 1992 to renovate the Post Anaesthesia Care Unit at the Ottawa Civic Hospital, Building #4, Level 2 and 3, 1053 Carling Avenue, Ottawa, Ontario.

2. **Description of Constrution**

   The Ottawa Civic Hospital is a 700 bed tertiary/quaternary care teaching hospital which provides specialty care in Neurosurgery, Vascular Surgery, Cardiac Care and disease of the Endocrine systems.

   The hospital recently completed a renovation to the Post Anaesthesia Care Unit, which included an upgrade to the Fire Alarm System.

3. **Dispute**

The dispute between the Applicant and Respondent concerns sufficiency of compliance with the technical requirements of Article 3.2.4.19. of the Building Code. At issue is whether strobe lights may be provided in the Intensive Care Unit, Operating Rooms and Post Anaesthesia Care Units to visually indicate the activation of the fire alarm system in lieu of audible devices such as bells or chimes.

4. **Provision of the Building Code**

Article 3.2.4.19. Audibility of Alarm Signals

1. Audible signal appliances forming part of a required fire alarm system shall be installed in a building so that alert signals, alarm signals and voice messages can be heard intelligibly throughout the floor area in which they are installed.
2. If a fire alarm system is required, audible signal appliances shall be located in a service space referred to in Sentence 3.2.1.1.(7) and shall be connected to the fire alarm system.

5. **Applicant's Position**

The Applicant submitted that the population of patients that are served by the hospital, includes cerebral aneurism repairs, cerebral tumour surgery, aggressive head and neck surgery (usually cancer related), high risk vascular surgery etc.

The Applicant submitted that common to all of these problems is the very real risk of post operative haemorrhage and/or stroke - the risk of which is directly affected by the patient's blood pressure, particularly intra-cranial blood pressure.

The Applicant submitted that when the new fire alarm sounds, the natural startle reflex of the patient causes an immediate rise in blood pressure, resulting in a situation in which the upgraded fire alarm system designed to make the environment safer, actually presents a very real life safety risk.

The Applicant submitted that speaker volumes have been lowered as a trial, however, the hospital has been unable to reach a satisfactory situation.

The Applicant appealed to the Building Code Commission for their endorsement of their proposal to substitute strobe lights in lieu of bells/chimes in the areas affected which include, Operating Rooms, Post Anaesthesia Care Units and Intensive Care Unit areas. Bells and chimes will remain in support areas where they do not pose a hazard to the patient population.

The Applicant proposed to situate the strobe lights throughout the affected areas. Audible warning devices would be provided at the nursing stations. The nose level of the devices would be to an effective level agreed upon with the City of Ottawa building department.

6. **Chief Building Official's Position**

The Respondent submitted that Sentence 3.2.4.4.(2) of the Building Code requires an alarm signal to sound upon the activation of the second stage of the manual pull station of the fire alarm system. Sentence 3.2.4.19.(1) of the Building Code requires alarm signals to be heard intelligibly throughout the floor area in which the signal devices are located.

The Respondent further submitted that while they understand the concerns raised, the municipality does not have the authority to allow the audible devices (i.e. bells/chimes) to be disconnected from the fire alarm system.

7. **Commission Ruling:**

It is the decision of the Building Code Commission that providing strobe lights conforming to U.L.C. S526-M87 in the Intensive Care Unit, Operating Rooms and Post Anaesthesia Care Units to visually indicate the activation of the fire alarm system in lieu of audible signalling devices provides sufficiency of compliance with Article 3.2.4.19. of the Building Code.

8. **Reasons:**
   i. The audible signals will be sounded at continually staffed locations.
   ii. Staff working in these areas are trained to recognize the fire alarm visual signals and take appropriate action for the safety of the patients.
   iii. Evidence indicated that an audible signal could have a detrimental impact on the health of patients at the subject locations.

Dated at Toronto, this 14th day, in the month of June, in the year 1996, for application number 1996-30.

RULING

1. **The Applicant**

   Mr. Anthony Auciello, President, Cachet Estate Homes Inc., is an applicant for a permit under the Building Code Act, 1992 to erect a temporary tent intended for use as a sales office for real estate development located at 259 Boake Trail, Thornhill, Ontario.

2. **Description of Constrution**

   The subject structure is a temporary tent to be used as a sales office for real estate. The Applicant proposes to construct a 5/8" thick plywood floor on 2x10 @ 24" o.c. Interior walls are proposed to be constructed to a height of approximately 8 feet, containing electrical wire with drywall finish on one side. The interior walls are to be constructed to within 24" of the outside fabric shin. The main entrance and rear exit doors are mounted in full frames with hardware.

   There are numerous display areas proposed inside the structure that are typical of those found in traditional builders sales pavilions.

3. **Dispute**

The dispute between the Applicant and Respondent concerns an interpretation of Section 3.1.6. of the Building Code. At issue is whether a tent to be used as a new home sales office and display area should be considered a temporary structure in accordance with the requirements of Subsection 3.1.6.

4. **Provision of the Building Code**

Subsection 3.1.6. Tents, Air-Supported Structures and Temporary Structures

3.1.6.1. Means of Egress

Tents, air-supported structures and temporary structures shall conform to Sections 3.3. and 3.4.

3.1.6.2. Application

1. Reserved
2. Air-supported structures shall not be used for Groups B, C or Group F, Division 1 major occupancies or for classrooms.
3. Air-supported structures shall be designed primarily as open floor space without interior walls, mezzanines, intermediate floors or similar construction.
4. A tent used for camping or personal use and not more than 30 m^2 (323 ft^2) in ground area is exempt from requiring a building permit and is exempt from compliance with this Code.
5. For the purposes of this Subsection, a temporary structure means a building or structure intended to be erected and used for a period of not more than 12 months.

3.1.6.3. Clearance to Other Structures

6. Except for tents used for camping and other personal uses and except as provided in Sentences (2),(3) and (4), every tent, air-supported structure and temporary structure shall conform to Subsection 3.2.3.
7. Tents and air-supported structures shall not be erected closer than 3 m (9 ft 10 in) to other structures on the same property except as provided in Sentences (3) and (4), and shall be sufficiently distant from one another to provide an area to be used as a means of emergency egress.

8. Tents and air-supported structures not occupied by the public need not be separated from one another and are permitted to be erected less than 3 m (9 ft 10 in) from other structures on the same property where such closer spacing does not create a hazard to the public.
9. Tents not more than 120 m² (1290 ft²) in ground area, located on fair grounds or similar open spaces, need not be separated from one another provided such closer spacing does not create a hazard to the public.

3.1.6.4. Clearance to Flammable Material

The ground enclosed by a tent or air-supported structure and for not less than 3 m (9 ft 10 in) outside of such a structure shall be cleared of all flammable material or vegetation that will carry fire.

3.1.6.5. Flame Resistance

Every tent and all tarpaulins and decorative materials used in connection with tents and air-supported structures shall conform to CAN/ULC S-109-M, "Standard for Flame tests of Flame-Resistant Fabrics and Films".

3.1.6.6. Reserved

3.1.6.7. Design of Framing and Support

The supporting framing structure and anchorage system of all tents more than 225 m² (2420 ft²) in ground area shall be designed by a professional engineer.

3.1.6.8. Design of temporary Structures

10. Except for tool sheds or similar structures, the structural components of a temporary structure shall be designed in conformance with
    a. Subsection 4.1.6. for the intended use,
    b. Subsection 4.1.7. for the snow and rain, and
    c. Subsection 4.1.8. for wind.

5. **Applicant's Position**

The Applicant submitted that the structure is a temporary tent complying with Subsection 3.1.6. of the Building Code.

The Applicant stated that the structure was erected in May and will be removed no later than the end of September 1996.

The Applicant stated that except for snow load design the tent meets the requirements for temporary structures in Article 3.1.6.8. of the Building Code.

6. **Chief Building Official's Position**

The Respondent submitted that the use and interior construction proposed by the Applicant was not contemplated under the tent, air- supported structure and temporary structure provisions in Subsection 3.1.6. of the Building Code.

The Respondent stated that the structure does not comply with Subsection 4.1.6. for the intended use, nor Subsection 4.1.7. with respect to snow and ice loading.

The Respondent submitted that the structure does not qualify as a tent due to the interior walls, floor and corridors and the construction requirements in Article 3.1.6.8. of the Building Code for temporary buildings must apply.

7. **Commission Ruling:**

It is the decision of the Building Code Commission that the new sales office and display area provides sufficiency of compliance with Subsection 3.1.6. of the Building Code provided the occupancy period is limited to a time when snow loading under Subsection 4.1.7. would not be applicable.

8. **Reason:**

Evidence was provided to demonstrate that the provisions of Subsection 4.1.7. and 4.1.8. have been addressed for wind and rain.

Dated at Toronto, this 12th day, in the month of June, in the year 1996, for application number 1996-29.

RULING

1. **The Applicant**

   Mr. Mark Kane, General Manager Eastern Canada, Carpenter Co., Vaughan is an applicant for a permit under the Building Code Act, 1992 to construct an addition to an existing medium hazard industrial occupancy located at 500 Hanlan Road, Vaughan, Ontario.

2. **Description of Constrution**

   The proposed addition is a one storey noncombustible building classified as a Medium Hazard Industrial Occupancy (i.e. Group F, Division 2). The building is provided with a sprinkler system, fire alarm system and standpipe and hose system. The building area is as follows:

Existing	25,612 m² (275,697 ft²)
Addition	5,070 m² (54,525 ft²)
Total	30,682 m² (330,272 ft²)

   The exposing building face of the addition that faces the CNR right-of-way has a variable height of 10 to 10.5 metres and is 67.8 metres long. The limiting distance from the wall in question to the property line is 15.25 metres. The wall is proposed to be constructed of metal panels on a steel frame.

3. **Dispute**

The dispute between the Applicant and Respondent concerns sufficiency of compliance with the technical requirements of Sentence 3.2.3.7.(2) of the Building Code. At issue is whether a wall adjacent to a CNR right of way may be constructed of metal panels on a steel frame in lieu of providing a 2 hour fire resistant rating.

4. **Provision of the Building Code**

Article 3.2.3.7.(2) Construction of Exposing Building Face

2. Except as permitted in Article 3.2.3.9., where a limiting distance shown in Table 3.2.3.B. for a Group E, or Group F, Division 1 or 2 occupancy classification is such as to permit an exposing building face to have unprotected openings of

b. not more than 10 per cent of the exposing building face, the exposing building face shall be of noncombustible construction having a fire-resistance rating of not less than 2 h and be clad with noncombustible cladding,
c. more than 10 per cent but not more than 25 per cent of the exposing building face, the exposing building face shall have a fire-resistance rating of not less than 2 h, and be clad with noncombustible cladding, and
d. more than 25 per cent but less than 100 per cent of the exposing building face, the exposing building face shall have a fire-resistance rating of not less than 1 h.

2. **Applicant's Position**

The Applicant submitted that the north wall of the addition is proposed as a non-combustible, metal panelled wall on a steel frame. The adjacent property is a CNR right of way and the nearest rail line is 29 metres from the building.

The Applicant submitted that the existing building faces the same CNR right of way. The wall in dispute is in the same plane as the existing wall which was not required to have a 2 hour fire resistance rating. The existing wall is 265 metres long.

The Applicant submitted that the CNR have confirmed they are not going to build on the right of way. The Applicant objects to the requirement of providing a 2 hour fire resistance rating.

3. **Chief Building Official's Position**

The Respondent submitted that the north wall of the addition is approximately 15 metres from the property line. Therefore, the north exterior wall of this addition requires a 2 hour fire resistance rating and be clad with non-combustible cladding in accordance with Clause 3.2.3.7.(2)(b) of the Building Code.

The Respondent further submitted that the CNR right of way is not a street by definition under Article 1.1.3.2. and therefore Clause 3.2.3.9.(2) of the Building Code is not applicable.

4. **Commission Ruling:**

It is the decision of the Building Code Commission that providing a wall of metal panels on a steel frame in lieu of providing a 2 hour fire resistant rating adjacent to a C.N.R. right of way does not provide sufficiency of compliance with Sentence 3.2.3.7.(2) of the Building Code.

5. **Reasons:**

ii. No alternatives were offered to provide sufficiency of compliance.
iii. The adjacent property is not considered a street for the purposes of Article 3.2.3.9. of the Building Code.

Mr. Steve Penna
Technical Supervisor
City of Vaughan
For the Respondent

RULING

1. **The Applicant**

   Mr. J. Nemeth, Project Manager, Magna, 455 Magna Drive, Aurora is the holder of a permit under the Building Code Act, 1992 to construct an addition to an existing industrial building for the purposes of sheltering scrap metal at 455 Magna Drive, Aurora, Ontario.

2. **Description of Constrution**

   The subject building is a one storey Medium Hazard Industrial Occupancy (i.e. Group F, Division 2) with a building area of 7702 m² (82906 ft²) used for the manufacturing of automobile parts. The building is also provided with a fire alarm system and an automatic sprinkler system.

   The Applicant proposes to construct an unsprinklered 223 m² (2400 ft²) addition for the storage of scrap metal. The addition is partially open to the outdoors. There is a 2 hour fire separation between the existing building and the scrap metal storage addition.

3. **Dispute**

   The dispute between the Applicant and Respondent concerns sufficiency of compliance with the technical requirements of Article 3.2.2.52. of the Building Code. At issue is whether the

proposed non-combustible addition being used for the shelter of scrap metal requires sprinkler protection.

4. **Provision of the Building Code**

Article 3.2.2.52. Industrial Buildings, Division 2 up to 4 Storeys

1. A building classified as Group F, Division 2 shall conform to Sentence (2) provided the building
   a. is not more than 4 storeys in building height,
   b. if unsprinklered, has a building area not more than the value in Table 3.2.2.T., and
   c. if sprinklered, is not more than twice the area limits of Clause (b).

No. of Storeys	Unsprinklered Maximum Area, m² (ft²)		
	Facing 1 Street	Facing 2Streets	Facing 3 Streets
1	3 200 (34 200)	4 000 (43 000)	4 800 (51 000)
2	1 600 (17 200)	2 000 (21 500)	2 400 (25 800)
3	1 070 (11 500)	1 340 (14 400)	1 600 (17 200)
4	800 (8 610)	1 000 (10 800)	1 200 (12 900)
Column 1	2	3	4

2. The building shall be of combustible or non-combustible construction used either singly or in combination, and
   a. floor assemblies shall be fire separations with fire-resistance rating of not less than 45 min,
   b. mezzanines shall have, if of combustible construction, a fire-resistance rating of not less than 45 min,
   c. roof assemblies shall have, if of combustible construction, a fire-resistance rating of not less than 45 min, except that in buildings not more than 1 storey in building height, the fire-resistance rating is permitted to be waived provided that the roof assembly is constructed as a fire-retardant treated wood roof system conforming to Article 3.1.14.1., and
      i. if unsprinklered, the building area is not more than

1600 m2 (17,100 ft²) if facing 1 street
2000 m² (21,5000 ft²) if facing 2 streets, or
2400 m² (25,800 ft²) if facing 3 streets, and

ii. if sprinklered, the building area is not more than twice the area limits of Subclause (i) (see Article 3.2.2.12. for supervised sprinkler systems), and

d. all loadbearing walls, columns and arches supporting as assembly required to have a fire resistance rating shall have a fire-resistance rating of not less than 45 min or shall be of noncombustible construction, except that such members and assemblies supporting a fire separation shall have a fire-resistance rating not less than that required for the supported assembly.

5. **Applicant's Position**

The Applicant submitted that the buildings sprinkler system need not be extended to the addition. The addition is used only for the temporary storage of scrap metal from the manufacturing process and is open to the outdoors.

The Applicant stated that the addition is structurally independent of the existing building. The Applicant stated that there is good fire fighting access to the addition.

The Applicant proposed to install heat detection devices connected to the fire alarm system in lieu of sprinklering the addition.

6. **Chief Building Official's Position**

The Respondent submitted that Article 3.2.2.52. of the Building Code requires the existing building to be protected by a sprinkler system. Therefore, the 223 m² addition must also be protected by a sprinkler system.

The Respondent submitted that in accordance with Sentence 3.2.5.13.(1) of the Building Code the installation of a sprinkler system must comply with NFPA 13.

The Respondent also submitted that NFPA 13, Sentence 1-6.1 states "a building, when protected by a automatic sprinkler system installation, shall be provided with sprinklers in all areas".

The Respondent stated that NFPA 13 does not require a sprinkler system for a canopy over noncombustible storage. The Respondent stated that this structure could not be considered a canopy due to it being enclosed on three sides.

The Respondent also stated that the building permit was issued subject to the addition being protected by a sprinkler system.

7. **Commission Ruling:**

It is the decision of the Building Code Commission that the unsprinklered shelter open on one side for noncombustible scrap metal storage provides sufficiency of compliance with Article 3.2.2.52. of the Building Code and the exceptions provided for sprinkler protection of exterior roofs or canopies in NFPA 13 provided that a 2 hour separation is provided between the existing building and shelter, and heat detectors connected to the fire alarm system are provided in the shelter.

8. **Reasons:**
   i. The enclosure is used only for noncombustible scrap metal storage.
   ii. The shelter is open on one face and access for fire fighting purposes is provided by a fire route along the open face of the shelter.
   iii. The shelter is separated by a 2 hour fire separation from the existing building.
   iv. Additional heat detection for early warning is provided in the shelter connected to the fire alarm system.
   v. It is the opinion of the Building Code Commission that the noncombustible storage shelter with one side open for noncombustible storage does not create an unsafe fire risk.

DATE OF RULING

July 9th, 1996

APPEARANCES

Mr. George Kotsilidis, Manager
Real Estate Operations
Toronto Dominion Bank
For the Applicant

RULING

1. **The Applicant**

   Mr. Chuck Lunau, General Manager, W.A. Stephenson Construction Managers Inc., Richmond Hill is the holder of a permit under the Building Code Act, 1992 to construct a one storey building for use by the Toronto Dominion Bank at 370 Simcoe Street, Beaverton, Ontario.

2. **Description of Constrution**

   The subject building is a one storey noncombustible Group D occupancy having a building area of 337.4 m² (3,631.8 ft²).

   The Applicant proposed to install an illuminated "TD" logo sign on the east face of the building. The sign will be located near the top at the south end of the east exterior wall. The sign will project 127 mm (5 inches) from the wall face and the sign bottom will be about 3.2 m (10 ft 5 in) above the surface of a side walk.

   There is a 0.9 m (3 ft) wide concrete side walk along the east side of the subject building. The side walk abuts the private lane of the Post Office building located on the adjacent property. Also, there is a continuous handrail that projects 76 mm (3 in) from the wall face of the bank building.

   At the entrance to the private lane, the separation between the bank building and the adjacent postal building is 3.8 m (12 ft 6 1/4 in). The dimension between the edge of the sidewalk and the west face of the postal building is 2.9 m (9 ft 6 1/4 in). The top of the sidewalk is at the same elevation as the top of the private lane.

3. **Dispute**

The dispute between the Applicant and Respondent concerns sufficiency of compliance with the technical requirements of Sentence 3.8.5.2.(2) of the Building Code. At issue is the proposed installation of the illuminated "TD" logo sign on the east side of the building adjacent to a private lane.

4. **Provision of the Building Code**

```
5. Sentence 3.8.5.2.(2)          Clearance for Exterior Signs
6.
7. (2)  Except as provided hereinafter, no sign face shall be
   erected
8.      within 600 mm (23 5/8 in) of the vehicular travelled
   portion of a
9.      private lane or roadway, or of a motor vehicle parking area
   unless
10.       the minimum vertical distance between grade and the bottom
   of the
        overhanging sign face is at least 4.25 m (13 ft 11 in).
```

11. **Applicant's Position**

The Applicant submitted that the proposed installation of the illuminated "TD" logo sign on the east side of the building adjacent to a private lane sufficiently complied with the Building Code.

The Applicant submitted that the sign is necessary to identify the bank for people approaching from the east. Also, there is a sidewalk and a handrail on the east side of the building that will help protect the sign from vehicles using the lane. The handrail projects 76 mm (3 in) and the sign depth is 127 mm (5 in).

The Applicant proposed to raise the height of the sign to not less than 12 ft to the bottom of the sign. The Applicant stated that the cube vans that use the lane way are approximately 9 ft high.

The Applicant stated that the Toronto Dominion Bank has a right of way agreement for the use of the sidewalk. They have agreed to keep the sidewalk free of snow and ice.

12. **Chief Building Official's Position**

The Respondent submitted that the sign face will be less than 600 mm (23 5/8 in) from a private lane and less than 4.25 m (13 ft 11in) to the bottom of the sign and does not conform to Sentence 3.8.5.2.(2) of the Building Code.

The Respondent submitted that the building next to the bank is a post office which has a large cube van delivering mail to the rear of the building. The van would be very close to the building. The ice and snow build-up in the winter could cause the van to tilt enough to damage or remove the sign.

The Respondent declined to attend the hearing.

13. **Commission Ruling:**

It is the decision of the Building Code Commission that the "TD" logo sign on the east side of the building does not comply with Sentence 3.8.5.2.(2) of the Building Code.

14. **Reasons:**

i. No commitment was provided that the height of vehicles using the private lane will be permanently restricted as identified in Sentence 3.8.5.2.(3) of the Building Code.

ii. No proposal was presented to limit the vehicular travelled portion of the right of way to meet the requirements of the Building Code.

Dated at Toronto, this 9th day, in the month of July, in the year 1996, for application number 1996-33.

For the Respondent

RULING

1. **The Applicant**

   Ms. Jacqueline Mills, Home Owner, 1 Jean Street, Toronto is an applicant for a permit under the Building Code Act, 1992 to construct interior alterations and a 2nd floor addition to a single family dwelling (i.e. house) at 1 Jean Street, Toronto, Ontario.

2. **Description of Constrution**

   The subject building is a three storey detached house located 0.3 m (1 ft) from the south property line. There is a 4.6 m (15 ft) right of way adjacent to the south property line to be used only for the passage of automobiles.

   The right of way is registered of the titles of both properties. The Applicant proposed that the spatial separation be extended to the south side of the right of way on the adjacent property.

3. **Dispute**

   The dispute between the Applicant and Respondent concerns sufficiency of compliance with the technical requirements of Sentence 9.10.14.12.(4) of the Building Code.

At issue is the determination of whether the limiting distance for the south wall of the building may be measured to the south side of the right of way on the adjacent property to maximize the permitted percentage of unprotected openings or glazed areas in the exterior wall.

4. **Provision of the Building Code**

5. Sentence 9.10.14.12.(4) Exposing Building Face of Houses

6.

7. (4) Where the spatial separation between dwelling units on adjoining

8. properties is registered on the titles of both properties, the

9. spatial separation may be calculated as if the dwelling units

were constructed on the same property.

10. **Applicant's Position**

The Applicant submitted that the property includes a registered right of way over the adjacent property. The right of way is registered on the titles of both properties as well as other neighbouring properties.

The Applicant stated that two additional bedroom windows are proposed to be installed on the 3rd storey. Also, a window of comparable size will be removed on the 1st storey. The window to be removed is set-back further than the proposed windows.

The Applicant stated that in order for the window openings to be permitted a limiting distance of 6 ft. 7 in. is required.

The Applicant submitted that the spatial separation should extend to the south side of the right of way on the adjacent property. Although, the Applicant stated that if the limiting distance was permitted to extend to the centre line of the right of way it would permit the installation of the proposed windows.

11. **Chief Building Official's Position**

The Respondent submitted that Sentence 9.10.14.12.(4) of the Building Code requires the limiting distance for the purposes of spatial separation to be registered on title. Titles of adjacent

property and the subject property indicate the use of the right of way exclusively for access purposes and not for limiting distance or spatial separation purposes.

The Respondent stated that if the limiting distance was shifted onto the neighbouring property (i.e. right of way) it would reduce the limiting distance to the rear of their properties.

12. **Commission Ruling:**

It is the decision of the Building Code Commission that providing a limiting distance of 7 ft. 0 in. from the south face of the building into the right of way provides sufficiency of compliance with Sentence 9.10.14.12.(4) of the Building Code.

13. **Reasons:**

i. A dedicated 15 ft. right of way is registered on the title of the adjacent properties to the south of the subject property.

ii. Existing windows on the exposing building face of approximately equivalent size to the new proposed windows will be blocked off and therefore there will be no significant increase in the percentage of glazed openings.

RULING

1. **The Applicant**

   Mr. H. Sinke, Project Co-ordinator, Abcott Construction Ltd. is an applicant for a permit under the Building Code Act, 1992 to construct an addition for coil storage and steel processing at the Namasco Blanking Centre, 546 Elgin Street, Brantford, Ontario.

2. **Description of Constrution**

   The existing one storey building and proposed addition will be utilized for coil storage and steel processing. The building is classified as a Low Hazard Industrial Occupancy (i.e. F-3).

   The building is not sprinklered nor does it have a fire alarm system. The building area of the complete building will be 7656 m² (i.e. 4084 m² existing and 3572 m² proposed).

3. **Dispute**

The dispute between the Applicant and Respondent concerns sufficiency of compliance with the technical requirements of Article 3.2.9.1. of the Building Code. At issue is a proposal to provide compensating fire protection measures in the form of fire extinguishers and a fire safety program in lieu of providing a standpipe and hose system.

4. **Provision of the Building Code**

Article 3.2.9.1. Standpipe and Hose Systems Where Required

1. Except as provided in Article 3.2.9.2., a standpipe and hose system shall be installed in every building that
    a. is more than
        i. 3 storeys in building height, or
        ii. 14 m (45 ft 11 in) in height measured between grade and the ceiling of the uppermost storey,
    b. is greater in building area than the area shown in Table 3.2.8.A. for the applicable building area shown on the Table where the building
        i. is not sprinklered, and
        ii. is not more than 14 m (45 m 11 in) high measured between grade and the ceiling of the top storey, or
    c. contains more than one storey below grade

5. **Applicant's Position**

The Applicant submitted that during the design process for the original building, the general contractor at that time applied for an exemption to the requirement for the standpipe and hose system on the basis of a previous BCC Ruling (i.e. 87-8-193).

The Applicant respectfully requested that the previous Ruling be extended to the proposed addition. The Applicant submitted the following information to support their application:

- The building is of noncombustible construction.
- The activity in this building is cold steel processing which does not create a likelihood of fire.
- The premises are equipped and/or will be equipped with adequate fire extinguishers.
- A fire safety committee has been organized and is operating in this facility.

The Applicant proposed to provide a fire access route and private hydrant(s) along the east face of the building as a compensating measure.

6. **Chief Building Official's Position**

The Respondent submitted that the existing 4,084 m² building was granted an exemption from the requirement to install a standpipe and hose system by the former Chief Building Official. This exemption was granted on the basis of BCC Ruling number 87-8-193 which involved a 5,120 m² building.

The Respondent submitted that an addition is now proposed to bring the total area of the building to 7,660 m². This building is now well beyond the scope of the building governed by Ruling 87-8-193.

The Respondent further submitted that Article 3.2.9.1. of the Building Code requires that a standpipe and hose system be installed in a one storey F-3 occupancy greater than 3,000 m² in building area and the total area of the building with the addition will be in excess of twice that area.

7. **Commission Ruling:**

It is the decision of the Building Code Commission that the building provides sufficiency of compliance with Article 3.2.9.1. of the Building Code provided a fire department access route and private hydrant(s) are installed along the east face of the building parallel to Plant Farm Road.

8. **Reasons:**

. The building contains a low fire load.
i. Additional fire extinguishers will be provided.
ii. A fire safety committee is in place and operational.
iii. No further additions to the building are contemplated.
iv. Additional fire department access and hydrant(s) will enhance fire fighting capability.
v. The installation of the hydrant(s) and access routes will require fire department pre-fire planning for the facility.

RULING

1. **The Applicant**

   Mr. Robert Dunlop, Home Owner, 222 Rosedale Heights Drive, Toronto is an Applicant for a permit under the Building Code Act, 1992 to renovate a kitchen in a two storey single family dwelling at 222 Rosedale Heights Drive, Toronto, Ontario.

2. **Description of Constrution**

   The subject building is a single family two storey brick house.

   The Applicant proposed to renovate the kitchen and install a sliding glass door in the rear, solid masonry wall of the house.

   The subject exposing building face is angled toward the side property line (e.g. approximately 45 degree to the line). The distance from the property line to the closest part of the glazed area is 2.1 m (6' 7"). The size of the proposed patio door is 6' 10" x 3' 6" (i.e. 2.2 m^2 or 23.9 ft^2).

3. **Dispute**

   The dispute between the Applicant and Respondent concerns an interpretation of the technical requirements of Articles 9.10.14.1. and 9.10.14.12 of the Building Code. At issue is whether the glazed area of the proposed sliding glass door in the subject exposing building face complies with the Spatial Separation requirements in the Building Code.

4. **Provision of the Building Code**

Article 9.10.14.1. Maximum Percentage of Unprotected Openings

1. Except as provided in Sentence (2) and in Articles 9.10.14.3. to 9.10.14.11., the maximum percentage of unprotected openings in an exposing building face shall conform to Table 9.10.14.A. or to Subsection 3.2.3., whichever is the least restrictive for the occupancy being considered.
2. An opening in an exposing building face not more than 130 cm2 (20 in²) shall not be considered an unprotected opening.

Article 9.10.14.12.

3. For the purposes of application of this Article
    a. the exposing building face may be divided into any number of portions and the fire resistance rating, type of cladding and glazed area limitations may be determined individually for each portion based on the limiting distance for each portion so divided,
    b. the exposing building face may be taken as the projection of the exterior wall onto a vertical plane located so that no portion of the exterior wall of the building is between the vertical plane and the line to which the limiting distance is established in Clause (a), and
    c. for the purpose of determining the actual percentage of glazed areas permitted in an exterior wall, the glazed area shall be projected onto the vertical plane established in clause (b).
4. Except as required in Article 9.10.14.3., in buildings containing only dwelling units in which there is no dwelling unit above another dwelling unit, the requirements of Article 9.10.14.11. do not apply provided that the exposing building face has a fire resistance rating of not less than 45 min where the limiting distance is less than 1.2 m (3 ft 11 in), and when the limiting distance is less than 0.6 m (23 5/8"), the exposing building face is clad with noncombustible cladding.
5. Glazed areas in the exposing building face referred to in Sentence (1) shall be permitted if the limiting distance is less than 1.2 m (3 ft 11 in) and shall be limited in conformance with the requirements for glazed areas in Table 9.10.14.A. where the limiting distance is 1.2 m (3 ft 11 in) or greater.

6. Where the spatial separation between dwelling units on adjoining properties is registered on the titles of both properties, the spatial separation may be calculated as if the dwelling units were constructed on the same property.

5. **Applicant's Position**

The Applicant submitted that the dispute revolves around a building permit for a kitchen renovation which included the installation of a sliding glass door in the rear, solid masonry wall of a home built in 1927.

The Applicant submitted that:

a. the building code is somewhat more restrictive for buildings whose walls are not parallel to the lot line, but more importantly,
b. the lot line in question is the side lot line for the applicant however, it is the rear lot line for the house on the adjoining lots. The City of Toronto Zoning By-law prohibits a building to be constructed closer than 7.5 m to the rear lot line of the adjacent properties.

The Applicant submitted that the according to the National Research Council Commentary on Part 9 of the National Building Code, the original calculations on which the requirements for spatial separation were based were for distances between buildings. A building permit however, only regulates the property on which it was issued, and not on the adjacent properties. The calculated distances were therefore halved, and measured to the property line.

The Applicant submitted that while it is perfectly reasonable for the Building Code to be written in this manner, it is not applicable in this circumstance.

The Applicant submitted that spatial separations are required to reduce thermal radiation and radiation intensity varies inversely as the square from the distance of the source (i.e. if the distance is doubled, the radiation intensity will only be 25%) there will always be more than sufficient spatial separation in this instance. Therefore, the Applicant contends that compliance with the Building Code is being met and a fire door is not required.

Furthermore, the Applicant submitted that the house in question has a fire detection system connected to a central station. The fire department response time should be less than the National Building Code assumption of 15 to 20 minutes.

6. **Chief Building Official's Position**

The Respondent submitted the Applicant proposes to add a new unprotected opening in an existing wall facing a property line. Unprotected openings in the same wall already exist less than 1.2 metres to the property line.

The Respondent lacks the authority to deviate from the Building Code.

The Respondent declined to appear before the Building Code Commission at the hearing.

7. **Commission Ruling:**

It is the decision of the Building Code Commission that the installation of a sliding glass door in the subject exposing building face provides sufficiency of compliance with Articles 9.10.14.1. and 9.10.14.12. of the Building Code considering the location and angle of the property line.

8. **Reasons:**

. The building is provided with hard wired smoke alarms connected to a central monitoring station.

i. The property line is irregular and it is the opinion of the Building Code Commission that the opening does not create an undue hazard.

ii. If only the first storey is considered the subject opening would satisfy the Building Code.

Dated at Toronto, this 1st day, in the month of August, in the year 1996, for application number 1996-36.

RULING

1. **The Applicant**

   Mr. Tony Romanin, Eminent Construction, Downsview is the holder of a permit under the Building Code Act, 1992 to construct a 12 storey residential apartment building at Grandview at Northtown, 88 Grandview Way, North York, Ontario.

2. **Description of Constrution**

   The subject structure is a 12 storey residential (i.e. Group C) apartment building of noncombustible construction. The building is provided with a fire alarm system and a standpipe and hose system.

   P.V.C. materials are used for the termination kit, 100 mm (4 inch) Tee and the 50 mm (2 inch) "Y" and cap for the condensation trap assembly for the hot water tank to be installed in each suite.

3. **Dispute**

   The dispute between the Applicant and Respondent concerns an interpretation of the technical requirements of Sentence 3.1.5.15.(1) and Clause 3.1.5.2.(1)(h) of the Building Code. At issue is

whether the use of PVC for the termination kit, 100 mm (4 inch) Tee and the 50 mm (2 inch) "Y" and cap for the condensation trap assembly of the water tank to be installed in each suite may be considered minor combustible components.

4. **Provision of the Building Code**

Sentence 3.1.5.15.(1) Combustible Piping Materials

1. Except as permitted in Clause 3.1.5.2.(1)(e), Sentence (2) and Article 3.1.5.20., combustible totally enclosed raceways, piping and tubing and associated adhesives are permitted to be used in a building required to be of noncombustible construction provided they
    a. have a flame-spread rating of not more than 25, except when concealed in a wall or a concrete floor slab, and
    b. when used in buildings described in Subsection 3.2.6., have a smoke developed classification of not more than 50, except when concealed in a wall or a concrete floor slab.

Clause 3.1.5.2.(1)(h)

2. The following minor combustible components are permitted in a building required to be of noncombustible construction:

    (h) similar minor components.

5. **Applicant's Position**

The Applicant submitted that the dispute involves the use of P.V.C. pipe for the termination kit and condensation trap for the hot water units.

The Applicant submitted that a 100 mm (4 inch) P.V.C. pipe is used in the exterior wall for the termination kit. Also, the 100 mm (4 inch) "T" and the 50 mm (2 inch) "Y" and cap for the condensation trap assembly are constructed of P.V.C.

It is the Applicant's contention that these are minor combustible components in the building.

6. **Chief Building Official's Position**

The Respondent submitted that the P.V.C. materials used for the termination kit and two fittings for the hot water tank to be installed in each unit do not comply with the Building Code.

7. **Commission Ruling:**

It is the decision of the Building Code Commission that the use of P.V.C. material for the termination kit, 100 mm (4 inch) Tee and the 50 mm (2 inch) "Y" and cap for the condensation trap assembly is considered a minor combustible component in accordance with Clause 3.1.5.2.(1)(h) and provides sufficiency of compliance with Sentence 3.1.5.15.(1) of the Building Code.

8. **Reasons:**
   i. i) The exposed P.V.C. components are limited and are located in dwelling units that are separated from each other by a 1 hour fire separation.
   ii. The materials meet the flame spread requirements in Clause 3.1.5.15.(1)(a) of the Building Code.
   iii. The termination kit will be limited to not more than 500 mm (20 inches). Most of the 100 mm (4 inch) diameter P.V.C. pipe will be enclosed in the exterior wall which is of noncombustible construction.
   iv. Much of the condensation trap will be filled with water.
   v. CPVC fittings for the appliance are not available in North America

Dated at Toronto, this 16th day, in the month of May, in the year 1996, for application number 1996-21.

The Respondent

RULING

1. **The Applicant**

   Mr. Peter Pijet, Manager, Concordia Club, Kitchener is an applicant for a permit under the Building Code Act, 1992 to erect a temporary festival tent having three links to ancillary buildings (i.e. new washroom facility, festival hall and kitchen building) at the Concordia Club, 429 Ottawa Street South, Kitchener, Ontario.

2. **Description of Constrution**

   The subject building is the Concordia Club Oktoberfest Festival tent. The Festival tent has a building area of 3779.5 m^2 (40,683.5 ft^2) and is classified as an Assembly Occupancy, Division 2 (A-2). The tent and ancillary buildings are provided with a fire alarm system interconnected with the Concordia Club building.

   A series of links join the tent to ancillary buildings (i.e. washrooms, permanent club building and kitchen facility). These links are permanent structures with 1 hour wall and roof assemblies and 45 minute closures. The links are intended to provide spatial separation between the various buildings, while permitting utility for staff and comfort for the patrons.

   The Applicant proposes to use the link between the festival tent and the kitchen area to serve food to patrons in the tent. The kitchen facility building and the link have a building area of 29 m^2 (312 ft^2) and 43 m^2 (463 ft^2) respectively. The proposed servery link will be separated from

the tent with another 1 hour assembly and the opening for the serving counter is equipped with a rated shutter, with a fusible link connected to an interconnected smoke alarm.

3. **Dispute**

The dispute between the Applicant and Respondent concerns sufficiency of compliance with the technical requirements of Article 3.2.3.20. and Sentence 3.1.6.3.(2) of the Building Code. At issue is whether a walkway between a temporary festival tent and a permanent kitchen facility may be used as a serving area for patrons in the tent.

4. **Provision of the Building Code**

Article 3.2.3.20. Walkway Between Buildings

1. Except as provided in Sentence 3.2.3.21.(2), where buildings are connected by a walkway, each building shall be separated from the walkway by a fire separation with a fire-resistance rating of not less than 45 min.
2. Except as provided in Sentence (3), a walkway connected to a building required to be of non-combustible construction shall also be of noncombustible construction.
3. A walkway connected to a building required to be of noncombustible construction is permitted to be of heavy timber construction provided
    a. not less than 50 per cent of the area of any enclosing perimeter walls is open to the outdoors, and
    b. the walkway is at ground level.
4. A walkway of noncombustible construction used only as a pedestrian thoroughfare and that is not required as an exit, need not conform to the requirements of Articles 3.2.3.14. and 3.2.3.15.

Sentence 3.1.6.3.(2) Clearance to Other Structures

2. Tents and air-supported structures shall not be erected closer than 3 m (9ft 10 in) to other structures on the same property except as provided in Sentences (3) and (4), and shall be sufficiently distant from one another to provide an area to be used as a means of emergency egress.

5. **Applicant's Position**

The Applicant submitted that the area of dispute is the building link between the festival tent and the permanent kitchen facility. At present there are three links in total.

The Applicant submitted that the two links serving the washroom facility and festival hall are used as required exits from the tent. The link between the temporary festival tent and kitchen building is not a required exit.

The Applicant submitted that the owners propose to place a serving counter across the opening at the tent/link face. Patrons would pass by this counter, cafeteria style, to receive there meals from serving staff. Within the link and adjacent to the counter would be placed steam tables, constantly replenished by other staff coming from the kitchen. Food is not cooked in the serving area. Beverage and food tickets are purchased elsewhere in the tent. The menu consists of 8 items and the tent can accommodate 3,000 patrons.

The Applicant submitted that prior to the new kitchen link being constructed there had been an existing structure in place that did not conform to any standards. This structure was used as a serving area between the kitchen and festival tent without any separation between the two.

6. **Chief Building Official's Position**

The Respondent submitted that at the time of building permit application the applicant indicated his desire to use the walkway for a thorough-fare for staff persons to carry food from the kitchen to serving tables. The Applicant later decided to use the walkway as a serving area.

The Respondent submitted that Article 3.2.3.20. of the Building Code permits the temporary tent to be considered a separate building if a noncombustible walkway structure is constructed connecting the tent to the permanent kitchen building. The minimum length of the walkway would need to be 3.0 metres to ensure compliance with Sentence 3.1.6.3.(2) of the Building Code.

The Respondent submitted that once the walkway becomes an occupied floor area the kitchen facilities must be considered "one building". This being the fact then the required minimum 3.0 metre clearance between the tent and the adjacent building has not been provided which is in contravention of Sentence 3.1.6.3.(2) of the Building Code.

7. **Commission Ruling:**

It is the decision of the Building Code Commission that using the link connected to the kitchen as a servery area provides sufficiency of compliance with Sentence 3.1.6.3.(2) and Article 3.2.3.20. of the Building Code provided that the roof assembly of the servery provides a 45 minute fire resistance rating.

8. **Reasons:**

   i. The kitchen and servery building is fire separated from the tent structure.
   ii. An interconnected fire alarm system has been provided for the tent and ancillary buildings that includes pull stations within the tent and a connection to the fire department.
   iii. The kitchen and servery building adjacent to the tent does not impede emergency egress from the tent.
   iv. It is the opinion of the Building Code Commission that considering the evidence submitted with respect to the additional safeguards provided, the kitchen and servery building adjacent to the tent does not create a hazard to the public.

Dated at Toronto, this 25th day, in the month of June, in the year 1996, for application number 1996-20.

RULING

1. **The Applicant**

   Mr. Bruce Barnett, Plant and Facilities Manager, North York Public Library is an applicant for a permit under the Building Code Act, 1992 to construct alterations and an addition to the Downsview Regional Library, 2793 Keele Street, North York, Ontario.

2. **Description of Constrution**

   The subject library is a one storey noncombustible building with a building area of approximately 1,176 m². The building is classified as an Assembly Occupancy, Division 2 (i.e. A-2). The building is provided with a fire alarm and detection system, but is not provided with neither an automatic sprinkler system nor a standpipe and hose system.

   Electromagnetic locking devices (EMLD) are proposed on three doors, two of which are exit doors equipped with panic type hardware. One of the subject exit doors is an exterior door and the other is a door providing access to an exit shaft.

3. **Dispute**

The dispute between the Applicant and Respondent concerns an interpretation of Sentences 3.4.6.15.(1) and 3.4.6.15.(4) of the Building Code. At issue is whether electromagnetic locking devices on two exit doors must release immediately upon activation of door release hardware.

4. **Provision of the Building Code**

Sentence 3.4.6.15.(1) Door Release Hardware

1. If a door is equipped with a latching mechanism, a device that will release the latch and allow the door to swing wide open when a force of not more than 90 N (20 lb) is applied to the device in the direction of exit travel shall be installed on
    a. every exit door from a floor area containing a Group A occupancy having an occupant load of more than 100 persons,
    b. every door leading to an exit lobby from an exit stair shaft, and every exterior door leading from an exit stair shaft in buildings having an occupant load of more than 100 persons, and
    c. every exit door from a floor area containing a Group F, Division 1 Occupancy.

Sentence 3.4.6.15.(4)

4. An electromagnetic locking device that does not incorporate latches, pins or other similar devices to keep the door in the closed position is permitted to be installed on an exit door, other than an exit door serving an elementary or secondary school or leading directly from Group F, Division 1 occupancy
    a. if the building is equipped with a fire alarm system conforming to Subsection 3.2.4.,
    b. if the locking device is installed as an ancillary device to the fire alarm system and releases immediately
        i. upon activation of the fire alarm signal,

        (i.1) where the exit door serves a hotel, upon activation of the alert signal where a two stage fire alarm system is installed or upon activation of the alarm signal where a single stage fire alarm system is installed,

        ii. in the event of a power failure or ground fault, and
        iii. upon actuation of a manually operated switch accessible only to authorized personnel,

c. if a manual pull station for the fire alarm system is located on the wall not more than 600 mm (235/8 in) from the door,
d. if, upon its release, the locking device must be actuation of the switch referred to in Subclause (b)(iii),
e. if a legible sign having the words EMERGENCY EXIT UNLOCKED BY FIRE ALARM is permanently mounted on the door, and
f. if the lettering on the sign required in Clause (e) is at least 25 mm (1 in) high with a 5 mm (3/16 in) stroke. (See Appendix A.)

5. **Applicant's Position**

The Applicant submitted that the proposed installation of electromagnetic locking devices in the desired locations conforms with Sentence 3.4.6.15.(4) of the Building Code.

The Applicant submitted that the buildings security system would be compromised if the electromagnetic locking devices release immediately upon activation of the door release hardware. Also, the level of safety intended by the Building Code is not compromised because the EMLD's are deactivated upon activation of the building's fire alarm system.

The Applicant stated that activation of the door release hardware does not include a 15 second time delay to deactivate the EMLD.

6. **Chief Building Official's Position**

The Respondent submitted that Sentence 3.4.6.15.(1) of the Building Code requires exit doors to open when door release hardware is activated.

The Respondent submitted that Sentence 3.4.6.15.(4) of the Building Code permits an electromagnetic locking device on exit doors provided the electromagnetic locking device is immediately deactivated when the door release hardware is activated. This is due to the independence of Sentence 3.4.6.15.(1) & (4). Therefore, conformance with both requirements is required.

The Respondent submitted that Section 813 of the BOCA National Building Code recognized special locking arrangements for security purposes, but these arrangements are not permitted in assembly occupancies due to higher occupant loads and the greater possibility of mass panic. The Occupant load of the subject building is 350 people as determined by NFPA 101.

7. **Commission Ruling:**

   It is the decision of the Building Code Commission that providing electromagnetic locking devices (EMLD's) on the required exit doors equipped with panic type hardware in the library building does not provide sufficiency of compliance with Sentence 3.4.6.15.(1) of the Building Code.

8. **Reasons:**

   i. No additional compensating features have been provided to enhance the provision for life safety.

   ii. The position of the Housing Development and Buildings Branch, Ministry of Municipal Affairs and Housing is that EMLD's installed on the required exit doors of the library equipped with panic type hardware must not negate the normal operation of the panic hardware on those doors, i.e. operation that will allow the doors to swing wide open immediately when a force of not more than 90 N (20 lb) is applied to the panic hardware in the direction of exit travel.

   iii. The Housing Development and Buildings Branch, Ministry of Municipal Affairs and Housing submitted that the entire Article 3.4.6.15. will be reviewed for the next edition of the Building Code and it is not expected that the philosophy regarding the use of EMLD's will change.

Dated at Toronto, this 12th day, in the month of June, in the year 1996, for application number 1996-17.

RULING

1. **The Applicant**

   Mr. William Pacey, Vice-President, National Store Planning, Shoppers Drug Mart, Mississauga is the holder of a permit under the Building Code Act, 1992 to construct a Distribution Centre for Shoppers Drug Mart at 6941 Kennedy Road, Mississauga, Ontario.

2. **Description of Constrution**

   The Shoppers Drug Mart's Distribution Centre is a single storey noncombustible building having a building area of approximately 48,724 m² (524,467 ft²) which is classified as a Group F Division 2 major occupancy. The building is used as a warehouse storing the typical products sold in Shopper Drug Mart retail outlets.

   A corner of the warehouse comprising approximately 1.1% of the floor area is allocated for the storage of Level 2 and Level 3 aerosol products such as deodorants, hair sprays, antiperspirants, etc. This area is separated from the remainder of the floor area by a chain link fence.

3. **Dispute**

The dispute between the Applicant and Respondent concerns sufficiency of compliance with the technical requirements of Sentences 3.3.1.2.(1), 3.3.1.10.(1) and 3.4.2.5.(2) of the Building Code. At issue is whether the aerosol storage cage in Shoppers Drug Mart's Mississauga Distribution Centre should comply with the provisions of Sentence 3.3.1.2.(1) or be considered a Group F, Division 1 Occupancy having to meet the fire separation, travel distance and door swing requirements of Sentences 3.3.1.10.(1) and 3.4.2.5.(2) of the Building Code.

4. **Provision of the Building Code**

Sentence 3.3.1.2.(1) Definitions of Words and Phrases

1. Where hazardous substances are used in connection with the activities of any occupancy other than as provided in Subsection 3.3.5. for a Group F, Division 1 occupancy, the storage, handling and use of such substances shall be in conformance with the provisions of the Ontario Fire Code made under the Fire Marshals Act, or in the absence of requirements pertinent to specific substances in the Ontario Fire Code, to good engineering practice such as is described in the publications of the National Fire Code of Canada 1990. (See Appendix A.) (See also Articles 3.1.1.19. and 6.2.2.5.)

Sentence 3.3.1.10.(1) Door Swing

2. Except as provided in Article 3.3.1.11., every door that opens into a corridor or other facility providing access to exit from a suite or room not located within a suite shall swing on a vertical axis and in the direction of exit travel where the room or suite is used or intended for
    a. an occupant load of more than 60 persons,
    b. a Group F, Division 1 occupancy, or
    c. a hazardous classroom in an elementary or secondary school.

Sentence 3.4.2.5.(2) Location of Exits

2. Except for a Group F, Division 1 occupancy, Sentence (1) need not apply if exits are placed along the perimeter of the floor area and are not more than 60 m (196 ft 10 in) apart, measured along the perimeter, provided each main aisle in the floor area leads directly to an exit.

5. **Applicant's Position**

The Applicant submitted that the building was designed and constructed to comply with the provisions of Article 3.2.2.55. of the Building Code for construction requirements and Sentence 3.4.2.5.(2) for the location of exits. This sentence is an exemption from complying with the travel distance requirements of the Code if the exits are placed along the perimeter of the floor and are not more than 60 m apart, measured along the perimeter, provided each main aisle in the floor area leads directly to an exit. This exemption applies to all occupancy classifications except for a Group F Division 1 occupancy.

The Applicant submitted that in the design of the Shoppers Drug Mart Distribution Centre, because it was impossible to comply with the travel distance requirements due to the very large size of the building, exits were placed along the perimeter of the floor area at 60 m intervals since the building was classified as a Group F, Division 2 warehouse.

The Applicant submitted that Table 3.1.2.A. of the Code refers to Appendix A for examples of major occupancy classifications. There is nothing in the Appendix under Group F Division 1 which indicates that an aerosol products storage area would constitute an F1 occupancy.

The Applicant submitted that the three aisles inside the aerosol storage cage each have sliding gates at both ends. The occupant load of the cage is only 1 or 2 employees, at certain times. The City of Mississauga indicated that "the doors leading from the area do not meet 3.3.1.10.(1) of the OBC".

Since there is no Group F Division 1 occupancy or an elementary or a secondary school involved and the occupant load is less than 60 persons the Applicant does not think that this Article is applicable. The Applicant, however, submitted that they agreed to install doors in the sliding gates, which will swing on a vertical axis in the direction of exit travel when pressure is applied. This complies with the requirements of Sentence 3.3.1.11.(1).

For structural rigidity of the sliding chain link fence gates, there will be a 2 inch high horizontal bar at the threshold of the swinging doors that will be located within the sliding gate. The Respondent has objected to this 2 inch bar at the threshold of the egress doors from the aerosol storage cage.

The Applicant submitted that he is not aware of any Regulation or Standard that prohibits such a horizontal member at the threshold of a swinging door located inside a sliding partition other than barrier-free requirements, if applicable.

The Applicant summarized it's position, as follows:

i. The aerosol storage cage in Shoppers Drug Mart's Distribution Centre is not a Group F, Division 1 occupancy. The indoor aerosol storage cage complies with the requirements of Sentence 3.3.1.2.(1) of the Building Code.
ii. The 25 m travel distance indicated in Clause 3.4.2.5.(1)(a) does not apply. The exits comply with Sentence 3.4.2.5.(2) of the Building Code.
iii. The door that swings on the vertical axis when a pressure is applied, which contains a horizontal member at the threshold and is installed on the sliding chain link gate for the aerosol storage cage, complies with Sentence 3.3.1.11.(1) of the Building Code.

Alternatively, considering the very limited number of employees that are in the cage temporarily and the familiarity with the surroundings, the Applicant requested the Building Code Commission consider the sufficiency of compliance of the aerosol storage cage with respect to the technical requirements of Sections 3.3. and 3.4 of the Building Code.

2. **Chief Building Official's Position**

The Respondent submitted that the subject of the dispute was with respect to the travel distance and door swing requirements of the aerosol storage area in the warehouse building.

The Respondent submitted that due to the quality and type of material products being stored in this warehouse building, this area should be classified as a Group F, Division 1 occupancy. Therefore, the travel distance and door swing should comply with the requirements of the Building Code for Group F, Division 1 occupancy from this chain link fenced area, in the case of an emergency situation.

3. **Commission Ruling:**

It is the decision of the Building Code Commission that the aerosol storage area provides sufficiency of compliance with the provisions of Sentences 3.3.1.2.(1), 3.3.1.10.(1) and 3.4.2.5.(2) of the Building Code provided the area meets all of the requirements of N.F.P.A. 30B for such use.

4. **Reasons:**
   i. The storage height is limited to 15 feet.

ii. Additional sprinkler protection is provided in accordance with N.F.P.A. 231 and is extended 20 feet beyond the segregated area.

iii. The proposed doors within the gates provided from the caged area allow for safe egress from the room.

iv. All openings in the fencing will be provided with self closing or automatic closing gates.

v. The occupant load of the storage area is limited.

Dated at Toronto, this 30th day, in the month of May, in the year 1996, for application number 1996-23. in the year 1996, for application number 1996-19.

For the Applicant

Mr. Mani Navabi
Chief Building Official
The Respondent

RULING

1. **The Applicant**

   Mr. Russell Flatt, Paramount Canada's Wonderland is the holder of a permit under the Building Code Act, 1992 to construct an outdoor wave action pool and ancillary buildings at the Splash Works, Paramount Canada's Wonderland, Vaughan, Ontario.

2. **Description of Constrution**

   The subject project involves the construction of an outdoor wave action pool and ancillary buildings as an expansion of the existing waterpark currently consisting of a number of water slides/receiving basins, washrooms, change rooms and shower facilities.

   The 2880 m² outdoor wave pool is an Assembly, Division 3 (i.e. A-3) occupancy.

3. **Dispute**

   The dispute between the Applicant and Respondent concerns sufficiency of compliance with the technical requirements of Subsection 3.11.9. of the Building Code. At issue is whether sufficient water closets and shower heads are provided for the wave action pool.

4. **Provision of the Building Code**

   Subsection 3.11.9. Dressing Rooms, Locker Facilities, and Plumbing Facilities for the Public Pools

1. Except as otherwise permitted in Sentences (2) and (3), every public pool shall be equipped with dressing rooms, locker rooms, shower heads, water closets, urinals, lavatories and drinking fountains which shall be designed, constructed and equipped to comply with Sentences (4) to (14).
2. Where a Class A pool is installed on the premises of a recreational camp, dressing rooms, locker rooms, shower heads, water closets, urinals, lavatories and drinking fountains are not required if
    a. dressing, water closet and shower facilities are conveniently available for bathers elsewhere on the premises, and
    b. foot sprays are provided in accordance with Sentence 3.11.3.1.(16).
3. Where a Class B pool is installed, dressing rooms, locker rooms, shower heads, lavatories, water closets, drinking fountains and urinals are not required if
    a. dressing, water closet and shower facilities are conveniently available elsewhere on the premises for bathers when the pool is open for use, and
    b. foot sprays are provided in accordance with sentence 3.11.3.1.(16).
4. The minimum number of water closets, urinals and lavatories shall be determined from Article 3.6.4.2. and Table 3.6.4.D. for an occupant load based on
    1. the formula in sentence 3.1.16.3.(1) for all public pools, except a wave action pool, or
    2. the formula in Sentence 3.1.16.3.(2) for a wave action pool.
5. A minimum of one shower head shall be provided for every 40 bathers.
6. Where dressing and locker rooms, water closets and urinals are provided in conjunction with a public pool, they shall be located in such a manner that bathers, after using them, shall pass through or by a shower area to reach the pool deck.
7. All shower heads shall be supplied with portable water at a pressure of at least 140 Kpa (20.3 psi).
8. The shower water system shall have one or more tempering devices capable of being adjusted to ensure that water supplied to shower heads does not exceed 400C (1040F).
9. Floors in washrooms, shower areas and passageways used by bathers shall slope to waste drains at not less than 1 per cent and shall be of hard surfaced materials that do not become slippery when wet.
10. Joints between floors and walls shall be covered in areas described in Sentence (9) and in dressing and locker rooms.
11. Hose bibs shall be provided in safe locations convenient for flushing down the walls and floors in washrooms, shower areas and passageways used by bathers.

12. Partitions or walls shall be provided to ensure privacy of dressing rooms, washrooms and shower areas.
13. The bottom of interior partitions in dressing rooms and washrooms shall be between 250 mm (97/8 in) and 350 mm (133/4 in) above the floor.
14. Dressing and locker room floors shall have non-slip surfaces that permit convenient and thorough cleaning and disinfecting.

5. **Applicant's Position**

The Applicant submitted that for the purpose of occupancy and provision of shower facilities the project is being considered an addition to the existing Splash Works facility. The analogy used is an addition to an existing building. The Applicant submitted that alternatively, the project could have been viewed as a stand- alone facility, but more washrooms and locker facilities would be required in the vicinity of the wave action pool.

The Applicant submitted the following summary of their position:

Occupancy Calculations:

Total Wave Pool Occupancy - 1,944 people; calculated using the formula in Sentence 3.1.16.3.(2) of the Building Code. The total projected occupancy for the balance of the waterpark is 3000 people (using park data from 1994 provided by Paramount Canada's Wonderland).

Total Water Park Site Occupancy: 4,944 people (Wave pool plus balance of site)

Washrooms:

The washrooms are sized based on the total estimated occupancy of the site, including the addition. Including the existing WCs (28 stalls, 14 per sex) and the new WCs (12 stalls, 6 per sex) the requirements of Table 3.6.4.D. of the Building Code are met. Based on the total occupancy of 4,944 people (2,472 per sex), 38 toilets (19 per sex) are required.

Shower Facility Calculations:

A public pool is defined in Part 1 of the Building Code as a "structure, basin or tank containing or intending to contain artificial body of water for swimming, water sport, water recreation or entertainment" but specifically excluding "pools that serve only as receiving basins for persons at the bottom of waterslides".

The Building Code states in Section 3.11.9.1.(5) that one shower head is required for every 40 bathers in a "public pool". As the pools serving the waterslides on the site are not public pools as defined by the Building Code, it is the Applicant's opinion that no showers are required for these pools. Therefore, the number of showers required for the total site should be based on the occupancy of the wave pool alone. Using this logic the Applicant determined the number of showers required to be 48 (1944 persons/40 bathers per shower head). This was provided on the original permit set, with 12 heads (6 per sex) shown on the new facility and plus the 36 in the existing facility (18 per sex).

The Applicant noted that the Waterpark differs from a stand-alone Waterpark in that it serves as only one activity in a larger facility and people therefore will stay in the Waterpark for a short period of time only and not all day as they would in a stand alone Waterpark. There are a large number of additional washrooms located throughout the rest of the park for public use.

6. **Chief Building Officials Position**

The Respondent submitted that the occupant load for the wave action pool is 1944 people. The Applicant requires 10 water closets per sex in accordance with Sentence 3.6.4.2.(15) and Table 3.6.4.D. and located in accordance with Sentences 3.11.9.1.(1) and (6) of the Building Code. The Applicant requires 48 shower heads on the wave action pool area.

The Respondent submitted that the applicant is only providing 6 water closets per sex in the immediate area of the wave action pool.

The distance between the existing washroom and shower facilities and the new facilities is approximately 210 m. Further, the distance from the new facilities to the edge of the wave action pool is approximately 75 m. Therefore, a bather may have to travel over 300 m to use a washroom.

The Respondent stated that this is a public health issue.

7. **Commission Ruling:**

It is the decision of the Building Code Commission that the additional 20 water closets and 48 showers are required by Article 3.11.9.1. of the Ontario Building Code. Furthermore, it is the decision of the Building Code Commision that providing no fewer than 12 water closets and 32 shower heads in the vicinity of the wave action pool with the remainding 8 water closets and 16

shower heads added to the existing facility at the entrance to the water park demonstrates sufficiency of compliance with the Article 3.11.9.1. of the Ontario Building Code.

8. **Reasons:**
   i. The wave action pool increases the occupant load of the water park by 1944 persons.
   ii. It is the opinion of the BCC that splitting the additional requirements for showers and water closets between the main entry and the site of the wave pool satisfies the intent of the Building Code for these facilities for bathers.

RULING

1. **The Applicant**

   Mr. Michael Murawnik, Building Manager, Standard Life, Ottawa is an applicant for a permit under the Building Code Act, 1992 to install electromagnetic hold-open device on certain doors to permit them to remain open at all times during normal working hours at the Canada Post Place, 750 Heron Road, Ottawa, Ontario.

2. **Description of Constrution**

   The subject building is a noncombustible building consisting of a 10 storey east tower and a 12 storey north tower linked by a two storey section. The building area is 60,385 m². The building is provided with a fire alarm and detection system, automatic sprinkler system, and a standpipe and hose system. Canada Post Corporation is the only tenant of this building. The subject doors that are proposed to be equipped with electromagnetic hold-open devices are identified as follows:

i. The double doors leading down the main corridor, from the North Tower to the East Tower, on the Ground Floor.
ii. The double doors leading down the main corridor, from the East Tower to the North Tower, on the Ground Floor.
iii. The double doors leading down the main corridor, from the East Tower to the North Tower, on the 1st Floor.

3. **Dispute**

The dispute between the Applicant and Respondent concerns sufficiency of compliance with the technical requirements of Article 3.1.8.12. of the Building Code. At issue is whether doors in the north and east lobby enclosure may be equipped with electromagnetic hold-open devices to permit them to remain open on a constant basis.

4. **Provision of the Building Code**

Article 3.1.8.12. Hold-Open Devices

1. Listed hold-open devices are permitted on doors in required fire separations, other than exit doors in a building more than 3 storeys in building height and doors in a vestibules required in Article 3.3.5.8., provided they are designed to release the door in conformance with sentences (2) to (4).
2. Except as provided in Sentences (3) and (4), hold-open devices permitted in Sentence (1) shall be designed to release
    a. upon a signal from a smoke detector located as described in Appendix B of NFPA 80, "Fire Doors and Windows", or from a smoke detector as required in Sentence 3.2.4.12.(1) for sleeping rooms in Group B occupancies, except that hold-open devices on doors other than exit doors, doors opening into public corridor and egress doors referred to in Sentence 3.4.2.4.(2) are permitted to be released by a sprinkler system or a heat-actuated device provided the door does not serve a group A, Group B or Group C occupancy and is not required to function as part of a smoke control system, and
    b. upon a signal from the building fire alarm system where a fire alarm system is provided, except that this requirement does not apply to a hold-open device that is designed to release by a heat-activated device in conformance with Clause (a).

3. In Group F, Division 2 and 3 occupancies, the hold-open devices in Sentence (1) are permitted to be designed to release upon a signal from a smoke detector located as described in Appendix B of NFPA 80, "Fire Doors and Windows".
4. In hospitals and nursing homes, a hold open-device on a door located between a corridor used by the public and an adjacent sleeping room shall be designed to release the door upon a signal from the fire alarm system when an alert signal is initiated within the same zone in Sentence 3.3.3.6.(6) or the same fire compartment in Sentence 3.3.3.7.(2).

5. **Applicant's Position**

The Applicant submitted that the owner/client and the tenant (Canada Post) have requested magnetic hold-open devices be installed on doors in the north and east lobby enclosure. The electromagnetic locking devices would be tied into the fire alarm system, connected to a smoke detection system and would release upon any power failure.

The Applicant submitted that the traffic between both towers is very high and has caused the replacement of hardware as well as doors due to overuse. The doors open within the two storey lobby space at one end and a 5 metre lobby at the other. The City of Ottawa considers the doors to be exit doors.

6. **Chief Building Officials Position**

The Respondent considers the door in question to be exit doors.

The Respondent submitted that Sentence 3.1.8.12.(1) prohibits the installation of hold-open devices on exit doors in buildings more than 3 storeys in building height. Exit doorways are identified in Article 3.4.4.4. as permitted openings in exit fire separations and furthermore Article 3.4.4.2. requires exit lobbies to conform to the requirements for exits, except as otherwise permitted.

The Respondent submitted that they are sympathetic to the concerns with respect to the maintenance of the door hardware, but it is not within their authority to permit the installation of the hold-open devices.

7. **Commission Ruling:**

It is the decision of the Building Code Commission that providing electromagnetic hold- open devices on the doors to the exit lobbies in the north and east exit towers provide sufficiency of

compliance with Article 3.1.8.12. of the Building Code provided the magnetic hold-open devices are installed in accordance with Clauses 3.1.8.12.(2)(a)&(b) of the Building Code.

8. **Reasons:**
   - . Evidence was provided that the lobbies are pressurized limiting smoke movement into this area.
   - i. The stairwells are separated from the lobby area by doors having a fire resistance rating as required by the Building Code.
   - ii. Both towers are sprinklered throughout.
   - iii. Evidence was provide that the stairwells are protected from smoke movement in accordance with Method "A" for high buildings.
   - iv. Evidence was provided that the high usage of these doors has a detrimental impact on the ability to continue to function as proper closures.

Dated at Toronto, this 14th day, in the month of June, in the year 1996, for application number 1996-18.

RULING

1. **The Applicant**

   Ms. Gloria Taylor, Clerk Administrator, Town of Paris is the holder of a permit under the Building Code Act, 1992 to construct a two storey addition to the public library at 12 William Street, Paris, Ontario.

2. **Description of Constrution**

   The subject building is a two storey noncombustible addition to an existing public library. An elevator serves both the existing and new addition.

   The building area of the existing portion (i.e. 231.4 m^2) and the addition (i.e. 226.4 m^2) is 457.8 m^2. A complete fire alarm system is installed throughout the building.

3. **Dispute**

   The dispute between the Applicant and Respondent concerns sufficiency of compliance with the technical requirements of Sentence 3.3.1.7.(1) of the Building Code. At issue is the installation of a fire alarm system, provision of a fire safety plan and a fire department response time of three

minutes in lieu of providing a fire-fighters elevator or dividing the floor area into 2 zones by fire separations.

4. **Provision of the Building Code**

Sentence 3.3.1.7.(1) Protection on Floor Areas with a Barrier-Free Path of Travel

1. Except as provided in Sentences (2) and (3), where a barrier- free path of travel is provided above or below the first storey in a building, every floor area having access shall
    a. be served by an elevator conforming to Sentences 3.2.6.9.(4) to (6), protected against fire in conformance with Clauses 3.2.6.9.(3)(b) or (c) and, in a building over 3 storeys in building height, protected against smoke movement in conformance with Sentence 3.2.6.2.(4) or
    b. be divided into not less than 2 zones by fire separations conforming to Sentences 3.3.3.6.(8) and (9) so that
        i. persons with physical disabilities can be accommodated in each zone,
        ii. the travel distance from any point in one zone to a doorway leading to another zone shall be not more than the value for travel distance permitted by Sentence 3.4.2.5.(1) for the occupancy classification of the zone, and
        iii. a barrier-free path of travel is provided to an exit.

5. **Applicant's Position**

The Applicant submitted that based on the following Sentence 3.3.1.7.(1) of the Building Code should not be applied to this building:

- The building area of 457.84 m² is less than half the 1,000 m² permitted in Sentence 3.2.2.21.(1) of the Building Code.
- The travel distance of 14 m is less than one half of the 30 m allowed under Clause 3.4.2.5.(1)(f) of the Building Code.
- The total occupant load of the entire building is never expected to exceed a maximum of 50 persons.
- The existing 92 year old building was completely brought up to current Building Code standards during the project.
- The addition is constructed of noncombustible construction.
- A complete fire alarm system, although not required by Article 3.2.4.1. is installed throughout the building.

- The fire safety plan requires two staff to jointly search the building for occupants in the event of a fire alarm. Trials show that this can be accomplished in two minutes.
- The fire department can respond within thee minutes of an alarm and remove disabled occupants without the use of the elevator.

6. **Chief Building Official's Position**

The Respondent submitted that a two storey addition to the original library includes an elevator serving both the existing and new addition. The elevator permits barrier free access thereby requiring the provision of protection on floor areas in accordance with Clauses 3.3.1.7.(1)(a) or (b) of the Building Code.

The Respondent submitted that the municipality does not have the authority to permit a condition that deviates from the Building Code. The use of equivalents regulated by Section 2.7 of the Building Code is not applicable.

7. **Commission Ruling:**

It is the decision of the Building Code Commission that the current design of the library addition provides sufficiency of compliance with the provisions of Sentence 3.3.1.7.(1) of the Building Code.

8. **Reasons:**

. A fire alarm system is provided for the building in excess of the Building Code requirements of Section 3.2.4.

i. The fire alarm system is monitored to notify the fire department in accordance with article 3.2.4.7. of the Building Code.

ii. A fire safety plan has been prepared designating supervisory staff and outlining the responsibilities for the safety of the physically challenged until the fire department arrives.

iii. The Applicant stated that the exit stairwell design permits the stairwell enclosure to be used as an area of refuge at all levels without impacting on the exiting.

iv. The fire department response time has been measured and will be less than 3 minutes in a fire emergency.

v. The building is small in size with a limited occupant load.

Dated at Toronto, this 21st day, in the month of May, in the year 1996, for application number 1996-16.

RULING

1. **The Applicant**

   Mr. Rob Gollanek, Estimator, The Daniels Corporation, Toronto is the holder of a permit under the Building Code Act, 1992 to construct a residential townhouse development containing 47 dwelling units situated in nine blocks known as Reesor's Marmill Townhouse Project, Markham, Ontario.

2. **Description of Constrution**

   The subject project is a residential townhouse development containing 47 dwelling units situated in nine blocks. The blocks contain between three and eight single family dwelling units that range in height between two and three storeys.

   The portion of the project that is the subject of this dispute are those units that offer third floor bedrooms, family rooms or dens. The applicant is proposing to use skylights in the roof to satisfy the egress requirements for an openable window from the third storey.

3. **Dispute**

   The dispute between the Applicant and Respondent concerns sufficiency of compliance with the technical requirements of Article 9.9.9.1. of the Building Code. At issue is whether an openable

roof window installed on a pitched roof satisfies the egress requirements for an openable window from the third storey.

4. **Provision of the Building Code**

Article 9.9.9.1. Travel Limit to Exits or Egress Doors

1. Except as provided in Sentences (2) and (3), every dwelling unit containing more than one storey shall have a sufficient number of exits or egress doors so that it shall not be necessary to travel up or down more than 1 storey to reach a level served by
    a. an egress door to a public corridor, enclosed exit stair or exterior passageway, or
    b. an exit doorway not more than 1.5 m (4 ft 11 in) above adjacent ground level.
2. Where there is no dwelling unit above or below another dwelling unit, the travel limit from a floor level in a dwelling unit to an exit or egress door may exceed 1 storey where that floor level is served by an openable window providing an unobstructed opening of not less than 1 m (3 ft 3 in) in height and 0.55 m (21 5/8 in) in width, located so that the sill is not more than 1 m (3 ft 3 in) above the floor and not more than 7 m (23 ft) above adjacent ground level.
3. The travel limit from a floor level in a dwelling unit to an exit or egress door may exceed 1 storey where that floor level has direct access to a balcony.

5. **Applicant's Position**

The Applicant submitted that an openable roof window installed on a pitched roof satisfied the egress requirements for an openable window from the third storey.

6. **Chief Building Official's Position**

The Respondent submitted that the proposed use of skylights to satisfy the egress requirements of an openable window from the third floor does not comply with the Building Code. The Respondent submitted that the positioning of the skylights makes egress or rescue from the floor area hazardous to both occupants and fire fighters.

The Respondent submitted that the skylights are located at the rear of the units and open onto the third storey roof which has a 9 in 12 slope. Typically the bottom edge of the proposed skylight is located approximately 2 m (6'-6") horizontally back from the edge of the roof, approximately 2.4 m (8'-0") up the slope of the roof and between 6.83 m and 7.28 m vertically above the finished grade measured at the rear wall of the subject unit. In addition, the skylights are positioned near a

proposed roof valley making them not immediately adjacent to the edge of the roof or ground below.

7. **Commission Ruling:**

   It is the decision of the Building Code Commission that the openable roof window on the pitched and gabled roof does not provide sufficiency of compliance with Article 9.9.9.1. of the Building Code.

8. **Reasons:**
   i. The steepness of the roof and the roof and gable configuration limit the accessibility to the roof window by fire department apparatus.
   ii. It is the opinion of the Building Code Commission that the proposal does not achieve the level of occupant safety intended by the Ontario Building Code.

Dated at Toronto, this 16th day, in the month of May, in the year 1996, for application number 1996-15.

For the Applicant.

Mr. Frank Spagnolo
City of Mississauga
For the Respondent

RULING

1. **The Applicant**

   The Rev. James Woolley, The Incumbent and Church Wardens of St. Thomas a Becket Anglican Church is the holder of a permit under the Building Code Act, 1992 to construct an addition consisting of a new worship space for the St. Thomas a Becket Anglican Church, 3535 South Common Court, Mississauga, Ontario.

2. **Description of Constrution**

   The subject project is a one storey addition consisting of a new worship space, plus new entrance, foyer, and ancillary rooms to be added to the existing church building which is shared by the Anglican and Presbyterian congregations.

   The building is classified as a Group A, Division 2 (i.e. church) occupancy. The addition is of combustible construction with an area of 462 m^2 giving a total building area of 1579 m^2. The new worship space is provided with fixed bench seating designed for a capacity of 295 people.

3. **Dispute**

   The dispute between the Applicant and Respondent concerns sufficiency of compliance with the technical requirements of Sentence 3.3.2.4.(4) of the Building Code. At issue is the width of aisles in the new worship space.

4. **Provision of the Building Code**

Sentence 3.3.2.4.(4) Aisles

Aisles shall terminate in a cross aisle, foyer or exit, and the width of such cross aisle, foyer or exit shall be not less than the required width of the widest aisle plus 50 per cent of the total required width of the remaining aisles that it serves.

5. **Applicant's Position**

The Applicant submitted that the subject of this dispute is the seating, aisles and exits from the worship area.

The Applicant submitted that the exit capacity of the worship area is more than adequate for the occupant load, and that the safety of persons using this space will not be diminished by a fixed seating layout instead of an approved non-fixed seating of indeterminate layout.

The Applicant submitted that the aisle with and exit locations provide adequate compliance with the Building Code.

The Applicant submitted that Sentence 3.3.2.4.(4) of the Building Code is not appropriately applicable to worship spaces where members regularly use the facility and are familiar with the exits. This Sentence is clearly intended for theatres and cinemas rather than spaces regularly used by same persons.

The Applicant submitted that applying Sentence 3.3.2.4.(4) to worship area reduces the seating capacity and negatively affects the liturgical practices of the users.

The Applicant further submitted that they have designed and built many places of worship similar in plan to the current application, and never experienced this Sentence being applied or interpreted in this way.

6. **Chief Building Official's Position**

The Respondent submitted that the reason for nonacceptance of the applicant's proposal is that the cross aisles and exit widths provided by the Applicant do not comply with Sentence 3.3.2.4.(4) of the Building Code.

7. **Commission Ruling:**

   It is the decision of the Building Code Commission that the width of the aisles for the addition to the existing church provides sufficiency of compliance with Sentence 3.3.2.4.(4) of the Building Code.

8. **Reasons:**
   1. The design provides for 5 exits from the room with exiting capacity for 862 persons, well above the occupant load of 295 and the exits are well distributed.
   2. The required width of aisles based on exiting capacity determinations is maintained to required exits from the room and provide an acceptable level of safety from this area.
   3. The provision of fixed seating does not increase the risk for the space over non fixed seating.

Dated at Toronto, this 21st day, in the month of May, in the year 1996, for application number 1996-12.

RULING

1. **The Applicant**

   Mr. Fred Schiedel, President, Schiedel Construction Incorporated is the holder of a permit under the Building Code Act, 1992 to construct a two storey building to be used as an automobile dealership at 995 Woodlawn Road West, Guelph, Ontario.

2. **Description of Constrution**

   The subject building is an unsprinklered two storey noncombustible building. The building area is 1158 m². The building does not contain a fire alarm system nor a standpipe and hose system. Air handling ducts are located within a conditioned return air plenum in the office and showroom area. The ducts do not meet the insulation, sealing and leakage test requirements of ASHRAE/IES 90.1-1989, "Energy Efficient Design of New Buildings Except Lowrise Residential Buildings".

3. **Dispute**

The dispute between the Applicant and Respondent concerns sufficiency of compliance with the technical requirements of Article 2.1.1.11. and Subclause 6.2.1.1.(1)(a)(v) of the Building Code. At issue is whether ducts in a return air plenum for a commercial building need be insulated and sealed in accordance with the requirements of ASHRAE/IES 90.1-1989, "Energy Efficient Design of New Buildings Except Lowrise Residential Buildings".

4. **Provision of the Building Code**

Article 2.1.1.11. Energy Efficiency

Except for buildings of residential occupancy within the scope of Part 9, farm buildings and areas of buildings intended primarily for manufacturing or commercial or industrial processing, the energy efficiency of all buildings shall be designed to good engineering practice such as described in ASHRAE/IES 90.1-1989, "Energy Efficient Design of New Buildings Except Lowrise Residential Buildings" and the "Guidelines for the Interpretation of ASHRAE/IES 90.1-1989" issued by the Ontario Buildings Branch of the Ministry of Housing.

Subclause 6.2.1.1.(1)(a)(v) Good Engineering Practice

1. Heating, ventilating and air-conditioning systems, including related mechanical refrigeration systems, shall be designed, constructed and installed to conform to good engineering practice appropriate to the circumstances such as described in
    a. the ASHRAE Handbooks as follows:

    (v) ASHRAE/IES 90.1-1989, "Energy Efficient Design of New Buildings Except Lowrise Residential Buildings".

5. **Applicant's Position**

The Applicant submitted that insulating and sealing the ducts in the conditioned return air plenum will not alter the energy required to condition this space.

The Applicant submitted that the intent of ASHRAE/IES 90.1 is to provide an energy efficient design of the building. The Applicant submitted that although there would be a decrease in temperature to the duct, the system now acts as a heat exchanger. There is a transfer of energy occurring at the duct/plenum interface, not a loss of energy.

The Applicant submitted that based on a cost approach, the amount of energy needed with or without the insulation would be insignificant. This analysis is based on the plenum being part of the system.

The Applicant submitted that on a cost analysis basis, the cost required to install the insulation will not pay for itself in a practical amount of time, if ever.

6. **Chief Building Official's Position**

The Respondent submitted that the Applicant proposed to use exception (b) of Article 9.4.8.3. of ASHRAE/IES 90.1 - 1989 to show that air handling ducts in a return air plenum do not need to be thermally insulated in accordance with Table 9-2.

The Respondent submitted that he does not accept the Applicant's proposal because uninsulated ducts in a ceiling plenum carrying air that has a supply air to ambient air temperature difference of over 15 degrees F will increase energy costs. This is inaccordance with interpretation IC 90.1-1989-7 of ASHRAE/IES 90.1 - 1989 dated April 15, 1992.

The Respondent does not accept the Applicant's proposal because Sentence 9.4.8.4.(b) of ASHRAE/IES 90.1 - 1989 requires that supply ductwork operating at static pressures from 0.25 to 2.0 in water column be sealed accordingly.

7. **Commission Ruling:**

It is the decision of the Building Code Commission that the building project provides sufficiency of compliance with Articles 2.1.1.11. and Subclause 6.2.1.1.(1)(a)(v) of the Building Code.

8. **Reasons:**
   i. Exception (b) of Article 9.4.8.3. of ASHRAE/IES 90.1 - 1989 permits uninsulated ducts where it can be shown that the heat gain to or heat loss from ducts without insulation will not increase energy costs.
   ii. In this application the supply ducts are considered to be located within the conditioned space which they serve.

Dated at Toronto, this 23rd day, in the month of April, in the year 1996, for application number 1996-10.

RULING

1. **The Applicant**

   Mr. Bob Brown, Supervisor of Corporate Development is an applicant for a permit under the Building Code Act, 1992 to construct a building containing four hockey rinks at 500 Ray Lawson Boulevard, Brampton, Ontario.

2. **Description of Constrution**

   The subject building is intended to be a Group A, Division 3 major occupancy (i.e. arena) with a variety of subsidiary occupancies.

   The buildings will contain four hockey rinks, each of which will be provided with change rooms for the players, referee rooms, public washrooms and snack bars on the main level. The second level will contain a restaurant and a viewing gallery for Rink 1 and 2. Rink 3 and 4 will not have viewing galleries associated within the rinks but will have a viewing area from the restaurant on the second level. Rinks 1 and 2 will also have viewing areas from the restaurant.

   The area of the open viewing galleries for Rinks 1 and 2 is approximately 530 m^2. The area of the upper lobby, restaurant, associated kitchen and administrative offices is approximately 780

m?. The area to the west of the viewing galleries, including a corridor which functions as an access to exit to the systems rooms and a mechanical room, is approximately 315 m².

The total building area of the structure is approximately 9239 m². The total of the second level, excluding the viewing galleries, is approximately 1050 m². The building will be fully sprinklered.

In addition to the second level, there are two roof top mechanical spaces which do not contribute to the overall height of the building in storeys. A third mechanical room is located on the west side of the building. This mechanical room has an area of 107 m?. This mechanical room is included in the 1050 m? second level area.

3. **Dispute**

The dispute between the Applicant and Respondent an interpretation of the technical requirements of Sentence 3.2.1.1.(2) and 3.2.1.1.(4) of the Building Code. At issue is whether a building containing four hockey rinks is to be classified as a single storey building with a mezzanine or whether it should be classified as a two storey building.

4. **Provision of the Building Code**

Sentence 3.2.1.1.(2) Exceptions to Building Height in Storeys

2. Space under tiers of seats in buildings of the arena type shall not be considered as adding to the building height provided such space is used only for a purpose incidental to the major occupancy of the building, such as for dressing rooms or concession stands.

Sentence 3.2.1.1.(4)

4. Except as provided in Sentence (5), a mezzanine shall not be required to be considered as a storey in calculating building height and need not conform to Sentence (3) where the aggregate area of the mezzanine floor does not exceed 10 per cent of the area of
    a. the suite in which it is located, where there is more than one suite in the storey, or
    b. the storey in which it is located, in all other cases.

5. **Applicant's Position**

The following information was submitted by the Applicant:

The original design of the building included a mezzanine which was approximately 9.9% of the first floor area. This second level discounted the viewing gallery seating and access to seating areas serving Rinks 1 and 2. In addition, in the original design, three roof top mechanical rooms were included. Two of the roof top mechanical rooms had areas of approximately 317 m². The third floor roof top mechanical room, because of its equipment, had a much larger area. During the course of design, the third or westernmost roof top mechanical room configuration was changed to permit the equipment to be installed vertically instead of horizontally. This required the mechanical room to extend above the roof for air intake purposes and below the roof for equipment installation. Initially, this equipment room was installed partially below the roof level but approximately 2 m above the floor surface of the second level. Further revisions to the equipment resulted in the mechanical room being dropped to the same level of the building with a large portion of the mechanical room extending through the roof in order to provide equipment height and air intake openings. Its area finalized at 107 m².

This change in the mechanical room resulted in the building being classified as a two storey building because the area contributed by the mechanical room as an additional area to the second level rendered the total second level area at approximately 11.4%. Without the mechanical room, the area of the second level is 10.2% of the first storey.

In addition, the building department was unwilling to allow the deduction of the walking surface which serve the viewing gallery seating in accordance with Sentence 3.2.1.1.(2). The position of the building department was that only the seating areas may be deducted, whereas the horizontal walking surfaces must be considered as contributing to the overall height of the building. This change brought the total area of the second floor to approximately 11.7% of the overall area of the first storey.

Conclusion: This type of building contains a second level of which less than 10% will be used as public access in order to watch events occurring on the hockey rinks below. The spaces which will only periodically be occupied by, at most, two or three individuals in a service capacity do not constitute any detriment to life safety of the overall building occupants or to fire fighters should a fire occur.

It is the opinion of the Applicant that the design as proposed, including full sprinklering of all arena spaces and all public amenity spaces throughout the entire building, along with the 2 h fire resistance rated enclosure for the mechanical room from the second floor where the Building Code only requires a 1 h fire resistance rated enclosure, and the full sprinklering of the

mechanical room, provides sufficiency of compliance with the life safety intent to the Building Code.

6. **Chief Building Official's Position**

The Respondent submitted that the aggregate area of the mezzanine is 1752.9 m? or 18.97% of the storey in which it is located.

The Respondent submitted that the definition of the floor area in the building code excludes exits, vertical service spaces and their enclosing assemblies. The exclusion of these spaces results in a mezzanine area of 1619.6 m? or 17.5% of the floor area.

The Respondent submitted that the exclusion of the service room and corridors still results in a mezzanine area slightly greater that the minimum 10% permitted.

The Respondent further submitted that the municipality's decision not to support the Applicant's proposal was based on the following factors:

- The building will be under three separate tenancies making a coordinated fire safety plan difficult.
- Provision for exiting. The minimum of two exits is provided from the restaurant/arcade area, one of which leads through a lobby. The occupant load of the restaurant/arcade is 300. The exit through the lobby also serves as on of the two exits provided for the viewing galleries of the 2 arenas (combined occupant load of 500).

2. **Commission Ruling:**

t is the decision of the Building Code Commission that the building provides sufficiency of compliance with Article 3.2.2.26. of the Building Code as a single storey with mezzanine.

3. **Reasons:**

ii. The sprinkler densities exceed those required by the building hazard classification.
iii. In addition the 1 hour fire separation provides sufficient structural integrity from fire for evacuation purposes.
iv. The mezzanine area does not significantly exceed 10% of the total floor area.

Dated at Toronto, this 16th day, in the month of April, in the year 1996, for application number 1996-07.

BCC Ruling No. 96-11-494

BUILDING CODE COMMISSION DECISION ON B.C.C. #96-11-494

IN THE MATTER OF Subsection 24(1) of the *Building Code Act, 1992.*

AND IN THE MATTER OF Sentence 3.4.6.15.(1) and Clause 3.4.6.15.(4)(c) of the Revised Regulation of Ontario 1990, Regulation 61, as amended by O.Regs. 400/91, 158/93, 160/93, 383/94 and 20/95 (the "Building Code").

AND IN THE MATTER OF an application by Mr. Ron Villeneuve, Vice- President, Cosmic Adventures Inc., Gloucester for the resolution of a dispute with Ms. Elizabeth Hilfrich, Chief Building Official, City of Gloucester, concerning: i) whether electromagnetic locking devices on five exit doors must release immediately upon activation of door release hardware in accordance with Sentence 3.4.6.15.(1) of the Building Code; and, ii) whether the installation of two manual pull stations for a fire alarm system incorporating electromagnetic locking devices beyond the maximum allowance of 600 mm from the door will provide sufficiency of compliance with Clause 3.4.6.15.(4)(c) of the Building Code, at Cosmic Adventures Inc., 1373 Ogilvie Road, Gloucester, Ontario.

Toronto, Ontario

DATE OF RULING

April 16th, 1996

APPEARANCES

Mr. Ron Villeneuve
Cosmic Adventures Inc.
Gloucester, Ontario
The Applicant

RULING

1. **The Applicant**

   Mr. Ron Villeneuve, Vice-President is the recipient of an order to comply under the Building Code Act, 1992 requiring: i) deactivation of electromagnetic locking devices on five exit doors equipped with panic type hardware when a force of not more than 90 N is applied to the panic hardware; and, ii) relocation of manual pull stations for the fire alarm system within 600 mm of the two gates equipped with electromagnetic locking devices.

2. **Description of Constrution**

   The subject building is a two storey noncombustible building with a building area of 2,531 m². The building has two tenants. Methot Mermaid Pools occupies 975 m² of the ground floor and 197 m² of the second floor. Cosmic Adventure Indoor Play centre occupies 1,556 m? of the ground floor and 337 m² of the second floor. A two hour fire separation is provided between the two tenants. The building is provided with a fire alarm and detection system and a sprinkler system, but not a standpipe and hose system.

   The main function of the Cosmic Adventure Indoor Play Centre is to provide supervised recreation and learning for children of all ages. To provide security against unauthorized entry and exit, electromagnetic locking devices have been installed on all exit doors of the tenant space.

3. **Dispute**

The dispute between the Applicant and Respondent concerns an interpretation of Sentence 3.4.6.15.(1) and sufficiency of compliance with the technical requirements of Clause 3.4.6.15.(4)(c) of the Building Code. At issue is: i) whether electromagnetic locking devices on five exit doors must release immediately upon activation of door release hardware; and, ii) whether the installation of two manual pull stations for a fire alarm system incorporating electromagnetic locking devices may be located beyond the maximum allowance of 600 mm from the door.

4. **Provision of the Building Code**

Sentence 3.4.6.15.(1) Door Release Hardware

1. If a door is equipped with a latching mechanism, a device that will release the latch and allow the door to swing wide open when a force of not more than 90 N (20 lb) is applied to the device in the direction of exit travel shall be installed on
    a. every exit door from a floor area containing a Group A occupancy having an occupant load of more than 100 persons,
    b. every door leading to an exit lobby from an exit stair shaft, and every exterior door leading from an exit stair shaft in buildings having an occupant load of more than 100 persons, and
    c. every exit door from a floor area containing a Group F, Division 1 Occupancy.

Clause 3.4.6.15.(4)(c)

4. An electromagnetic locking device that does not incorporate latches, pins or other similar devices to keep the door in the closed position is permitted to be installed on an exit door, other than an exit door serving an elementary or secondary school or leading directly from Group F, Division 1 occupancy

    (c) if a manual pull station for the fire alarm system is located on the wall not more than 600 mm (23 5/8 in) from the door.

5. **Applicant's Position**

i. Concerning sufficiency of compliance with Clause 3.4.6.15.(4)(c):

The Applicant requested permission to relocate two pull stations for the fire alarm system, beyond the maximum allowance of 600 mm from the door. This would only apply to the electromagnetic locking devices installed at the reception desk exit gates. The Applicant submitted that the gates and walls that separate the inside area from the outside area are only 900 mm high and the staff have problems keeping children from hopping over them at the best of times let alone if there was an emergency. The new placement would put the devices 1 metre away on the inside face of the counter, near the public address system of the emergency control centre. This area is manned during all hours of operation by trained personnel.

The Applicant submitted that the requirements of the Building Code locates the fire alarm pull station within easy reach of the average, inquisitive, impatient and excited 5 or 6 year old. The Applicant further submitted that in a test conducted on site, a dummy pull station was activated five times over a weekend despite increased awareness of the problem by staff.

The Applicant submitted that the reason for the appeal is simply a desire to reduce the possibility of accidental or malicious false alarm while providing maximum protection to our guests.

ii. Concerning an interpretation of Sentence 3.4.6.15.(1):

The Applicant submitted that if the panic type hardware is required to immediately disengage the electromagnetic locking devices it would be tantamount to having no egress security what so ever and invites the opportunity of a child wandering out unnoticed or even worse may create fertile ground for an abduction.

The Applicant submitted that they have taken the added precaution of installing an electromagnetic locking device de-activation keypad or a push button at each electromagnetic locking device location and in the event of an emergency a trained staff member would be responsible for releasing them should all other safe guards fail.

The Applicant also requested consideration to use a fifteen second time delay in the panic hardware to allow staff time to respond to the door in question.

2. **Chief Building Official's Position**

The Respondent submitted that Sentence 3.4.6.15.(1) of the building code requires exit doors to open when door release hardware is activated.

The Respondent submitted that Clause 3.4.6.15.(4)(c) of the building code requires a pull station to be located within 600 mm of a door equipped with an electromagnetic locking device.

The Respondent further submitted that the Applicant's proposals do not comply with the building code.

3. **Commission Ruling:**
   i. It is the decision of the Building Code Commission that the installation of electromagnetic locking devices (EMLD) on required exit doors equipped with release hardware (i.e. panic type hardware) provides sufficiency of compliance with Article 3.4.6.15. of the Building Code provided that:
      a. A force of not more than 90 N applied to the door opening hardware initiates an irreversible process that will release the locking device within 15 seconds and will not relock until the door has been opened.
      b. A deactivation key pad is installed at every door with EMLD which will release the EMLD immediately.
      c. A legible sign is permanently mounted on the exit door to indicate that the locking device will release within 15 seconds of applying pressure to the door release hardware.
      d. The EMLD is installed as an ancillary device to the fire alarm system and the installation, activation and resetting shall comply with the requirements of Sentence 3.4.6.15.(4) of the Building Code.
      e. Emergency lighting is installed in accordance with the Building Code at the exit doors with EMLD's to illuminate door signage.
      f. The EMLD's are not connected before a Fire Safety Plan is approved by the Chief Fire Official which identifies the installation of the EMLD's.
      g. All EMLD's will be capable of being released immediately from the emergency control centre which is continuously attended.
   ii. In addition, it is the decision of the Building Code Commission that the relocation of two pull stations to the reception desk exit gates at one metre away on the inside face of the counter of the emergency control centre provides sufficiency of compliance with Clause 3.4.6.15.(4)(c) provided the location is continuously attended.
4. **Reason:**

It is the opinion of the Building Code Commission that the conditions imposed above provide sufficient safeguards with respect to life safety recognizing the security needs of this particular use.

Dated at Toronto, this 19th day, in the month of April, in the year 1996, for application number 1996-08.

The Respondents

RULING

1. **The Applicant**

   Mr. Ross A. Smith, President is an applicant for a permit under the Building Code Act, 1992 to construct a three level open-air parking garage of approximately 6624 m? per floor, at King Street Parkade, King Street and Louis Street, Peterborough, Ontario.

2. **Description of Constrution**

   The subject building is a non-combustible two storey open-air parking garage of approximately 6624 m? in building area. The third level is an open roof deck that is used for parking vehicles.

   Hose bibs have been provided for the washing down of all floor levels. The designer proposed to connect all floor drains directly to an existing storm drainage system. The site is presently being used as a surface parking lot that drains to the storm system.

3. **Dispute**

   The dispute between the Applicant and Respondent concerns sufficiency of compliance with the technical requirements of Article 7.4.2.1. of the Building Code. At issue is the fact that a surface parking lot, or the open roof deck of a parking garage may be drained to a storm system while the covered floors of a parking garage must be connected to a sanitary drainage system.

4. **Provision of the Building Code**

Article 7.4.2.1. Connections to Sanitary Drainage Systems

1. Every fixture shall be directly connected to a sanitary drainage system, except that
    a. drinking fountains may be
        i. indirectly connected to a sanitary drainage system, or
        ii. connected to a storm drainage system provided that where the system is subject to backflow, a check valve is installed in the fountain waste pipe,
    b. laundry plumbing appliances may be indirectly connected to a sanitary drainage system,
    c. fixtures or plumbing appliances, other than floor drains, that discharge only clear water waste may be connected to a storm drainage system,
    d. the following devices shall be indirectly connected to a drainage system
        i. a device for the display, storage, preparation or processing of food or drink,
        ii. a sterilizer,
        iii. a device that uses water as a cooling or heating medium,
        iv. a water operated device,
        v. a water treatment device, or
        vi. a drain or overflow from a water system or a heating system,
    e. fixtures that have a hydraulic load of not more than 1 1/2 fixture units may be connected to a vertical section of a circuit vent provided
        i. the fixtures are located in the same storey as the fixtures served by the vent pipes,
        ii. not more than 2 fixtures are connected to the vent pipe, and
        iii. where 2 fixtures are not connected to the vent pipe, the connection is by means of a double sanitary TY fitting,
    f. fixtures that have a hydraulic load of not more than 1 1/2 fixture units may be connected to the vertical section of a yoke vent provided
        i. not more than 2 fixtures are connected to the vent pipe, and
        ii. where 2 fixtures are connected to the vent pipe, the connection is by means of a double sanitary TY fitting, and
    g. fixtures may be connected to a vent stack provided
        i. the total hydraulic load of the connected fixtures does not exceed 8 fixture units,

ii. at least 1 fixture is connected to a vertical portion of the vent stack and upstream of any other fixtures,

iii. no other fixture is connected down-stream of a water closet, and

iv. all fixtures are located in the lowest storey served by the vent stack.

2. The connection of a soil or waste pipe to a nominally horizontal soil or waste pipe or to a nominally horizontal offset in a soil or waste stack shall be respectively at least 1.5 m (4 ft 11 in) measured horizontally from the bottom of a soil or waste stack or from the bottom of the upper vertical section of the soil or waste stack that
   a. receives a discharge of 30 or more fixture units, and
   b. receives a discharge from fixtures located on 2 or more storeys.
3. No other fixture shall be connected to a lead bend or stub that serves a water closet.

5. **Applicant's Position**

The Applicant proposed to connect the floor drains from each of the three levels directly to an existing storm drainage system. The Applicant submitted that at issue is whether there is any difference in the waste water generated on the lower two floors (i.e. Levels P1 & P2) from that generated at the roof deck (Level 3).

The Applicant submitted that the intent of the Building Code would be met if all the garage floors were connected to the storm drainage system.

6. **Chief Building Official's Position**

The Respondent submitted that Sentence 7.4.2.1.(1) of the Building Code states that every fixture shall be directly connected to a sanitary drainage system. Fixture is defined in Article 1.1.3.2. and the definition includes floor drains. Clause (c) of 7.4.2.1.(1) allows for fixtures other than floor drains to discharge clear water waste to a storm drainage system. Clear water waste is also defined in Article 1.1.3.2.

The Respondent submitted that the reason for non-acceptance of the applicants proposal is that the drains serving the first and second floor of the parking garage are floor drains and therefore must be connected to the sanitary drainage system. The Respondent also submitted that it is questionable whether or not the discharge through these drains could be considered as clear water waste.

7. **Commission Ruling:**

It is the decision of the Building Code Commission that floor drains in the three level open air parking garage connected to the storm drain system provides sufficiency of compliance with Article 7.4.2.1.(1)(c) of the Building Code.

8. **Reasons:**

There is little difference between the waste water generated on the lower two parking floors and the waste water generated on the roof.

The parking garage will not be used for other purposes other than storage of automobiles.

RULING

1. **The Applicant**

   Mr. Larry Balaban, Vice-President Real Estate is the holder of a permit under the Building Code Act, 1992 to construct alterations to an existing office space and warehouse storage area at 90 Ronson Drive, Etobicoke, Ontario.

2. **Description of Constrution**

   The subject building is a sprinklered one storey noncombustible warehouse with subsidiary office space that is classified as a Medium Hazard Industrial Occupancy (Group F, Division 2). The building area is 7710 m^2.

   The Applicant proposed to enlarge their office space and construct a new wall separating the expanded office area from the warehouse storage area.

There is an existing wire fence separating the warehouse area from an adjoining warehouse space operated by another tenant. The municipal building department have issued an order to comply requesting the applicant erect a 1 hour fire separation between the two tenancies.

3. **Dispute**

The dispute between the Applicant and Respondent concerns sufficiency of compliance with the technical requirements of Article 3.3.1.1. of the Building Code. At issue is whether the existing chain link fence separating two tenants within a warehouse area must be replaced with a 1 hour fire separation.

4. **Provision of the Building Code**

Sentence 3.3.1.1. Separation of Suites

1. Except as permitted by Sentence (2), each suite in other than business and personal services occupancies shall be separated from adjoining suites by a fire separation having a fire- resistance rating of not less than 1 h, except that a fire- resistance rating of not less than 45 min is permitted where the fire resistance rating of the floor assembly in not required in Subsection 3.2.2. to be more than 45 min. (See also Subsection 3.3.3. for institutional occupancies, Article 3.3.4.2. for residential occupancies and Articles 3.1.8.7. for fire dampers.)
2. In sprinklered buildings, suites of business and personal services occupancy and mercantile occupancy that are served by public corridors conforming with Clause 3.3.1.4.(1)(c) are not required to be separated from each other by fire separations.

5. **Applicant's Position**

The Applicant submitted that the chain link fence that separates the two tenants has been in place since 1990. The Applicant also submitted that the building is fully sprinklered and that Compliance Alternative F27 in Table 11.2.3.F. of the Building Code permits non rated separations where the building is sprinklered.

6. **Chief Building Official's Position**

The Respondent submitted that two tenants in the warehouse area are separated by a chain link fence. Article 3.3.1.1. of the Building Code requires a minimum 45 minute fire separation between suites of industrial occupancy. The Respondent submitted that a chain link fence

provides neither a fire rating nor a fire separation. In sprinklered buildings, only suites of business and personal services and mercantile occupancies served by public corridors conforming with Clause 3.3.1.4.(1)(c) of the Building Code are exempt from requiring a fire separation from each other.

The Respondent submitted that a drawing forming part of the building permit application clearly identifies a rated demising wall (ULC W407) between the two tenants that satisfies Article 3.3.1.1. of the Building Code.

7. **Commission Ruling:**

   It is the decision of the Building Code Commission that a chain link fence does not provide sufficiency of compliance with the required fire separation between the two warehouse tenancies conforming to Article 3.3.1.1. of the Ontario Building Code.

8. **Reasons:**
   1. The compliance alternative F27 in Table 11.2.3.F. of the Building Code permits non rated separations where a building is sprinklered at public corridors separations, but not to required fire separations between suites.
   2. No evidence could be provided that a permit was ever issued for the installation of the chain link fence nor the date of the installation. The fence does impact on the egress requirements and would have been considered a material alteration for permit purposes.
   3. No confirmation could be provided by the applicant as to when the building would be restored to a single tenancy.

Dated at Toronto, this 15th day, in the month of April, in the year 1996, for application number 1996-09.

RULING

1. **The Applicant**

   Mr. Grant McBain, Vice President is an applicant for a permit under the Building Code Act, 1992 to connect a new building sewer to an existing private sewer at 2050 Victoria Park Avenue, North York, Ontario.

2. **Description of Constrution**

   The subject property is currently being occupied by a Sunoco gas station. There is an operating septic tank at the rear of the property. A one inch copper water service pipe was installed around 1975 with connection to a water main directly in front of the property on the west side of Victoria Park Avenue. Surface water flows overland to Victoria Park Avenue in accordance with a North York municipal by-law. The existing storm and sanitary sewers on the property were designed and built at the same time as the high-rise building at 21 Welsford Gardens, approximately 1965. There is a registered easement for both the storm and sanitary sewers to service the two commercial properties which front onto Victoria Park Avenue.

3. **Dispute**

The dispute between the Applicant and Respondent concerns sufficiency of compliance with the technical requirements of Sentences 7.1.6.1.(1), 7.1.6.2.(1) and 7.1.6.4.(1) of the Building Code. At issue is whether a new building sewer is permitted to be connected to an existing private sewer which is currently serving other buildings.

4. **Provision of the Building Code**

Sentence 7.1.6.1.(1) Sanitary Drainage Systems

1. Every sanitary drainage system shall be connected to a public sanitary sewer, a public combined sewer or a private sewage disposal system.

Sentence 7.1.6.2.(1) Storm Drainage Systems

2. Every storm drainage system shall be connected to a public storm sewage works, a public combined sewage works or a designated storm water disposal location but shall not be connected to a sanitary sewage works.

Sentence 7.1.6.4.(1) Separate Services

3. Piping in any building shall be connected to the public services separately from piping of any other building, except that an ancillary building on the same property may be serviced by the same service.

5. **Applicant's Position**

The Applicant submitted that the subject property is currently serviced by a septic system. The Applicant proposed to service the property with private storm and sanitary sewers which were installed in 1965.

The Applicant submitted that the existing storm and sanitary sewer are of sufficient capacity, depth and orientation to service the subject property.

Both the existing storm sewer and sanitary sewer are located within a 30 foot wide registered easement.

6. **Chief Building Official's Position**

The Respondent submitted that the Applicant proposed to service the new property by an existing private storm and sanitary sewer that is already servicing an apartment building and a commercial plaza.

The Respondent submitted that the proposal contravenes the Building Code. A direct connection is required from each property to the public sewer.

7. **Commission Ruling:**

   It is the decision of the Building Code Commission that the use of existing private sewers provide sufficiency of compliance with the requirement to connect to a public sewer in accordance with sentences 7.1.6.1.(1) and 7.1.6.2.(1) of the Building Code subject to engineering analysis that sufficient capacity exists in the private sewer system.

8. **Reasons:**
   1. A registered easement exists with both storm and sanitary sewers to permit the connection
   2. The private storm and sanitory sewers which serve 21 Welsford Gardens were designed in 1965 to service this commercial property which fronts onto Victoria Park Avenue.
   3. According to the consultants reports, both storm and sanitary sewers appear to be of sufficient capacity, depth and orientation to serve this property.

Dated at Toronto, this 15th day, in the month of April, in the year 1996, for application number 1996-06.

City of Mississauga
For the Respondent

RULING

1. **The Applicant**

   Mr. Les Cam, Parks and Recreation Department, City of Mississauga is an applicant for a permit under the Building Code Act, 1992 to construct a two storey complex of 12,000 m? containing one Olympic size rink, three professional size rinks, a licensed restaurant, snack bar, skills arcade, shop and toddler play area.

2. **Description of Constrution**

   The Four Rinks Arena is protected by automatic sprinklers throughout and is classified as a Group A, Division 3 occupancy. This two storey complex has a building area of 12,000 m². It containing four rinks, a licensed restaurant, snack bar, skills arcade, shop and toddler play area.

   The four rinks occupy the ground floor level and are arranged in quadrants with a lobby bisecting the complex for public access. Directly above the ground floor level is the second level lobby.

   In accordance with Article 3.2.2.27. of the Building Code fire separations would be required, as follows:

   - horizontal floor assembly, 2h fire resistance rating, second level lobby

- vertical wall assembly utilizing glazing and automatic sprinklers, meeting the horizontal separation, 2h fire resistance rating, second level lobby/overview of rinks since visual openings are desired to each rink.

The applicant is proposing the installation of tempered glazing and sprinklers on one side of the glazing in lieu of a 2 hour fire separation.

3. **Dispute**

The dispute between the Applicant and Respondent concerns sufficiency of compliance with the technical requirements of Clause 3.2.8.2.(6)(c) of the Building Code. At issue is whether an interconnected floor space is permitted in this Group A, Division 3 occupancy without conforming to the requirements of Articles 3.2.8.3. to Article 3.2.8.11. of the Building Code.

4. **Provision of the Building Code**

Sentence 3.2.8.2.(6) Exceptions to Special Protection

6. An interconnected floor space need not conform to the requirements of Articles 3.2.8.3. to 3.2.8.11. provided
   a. the interconnected floor space consists of the first storey, and the storey next above it, but not both,
   b. the interconnected floor space is sprinklered, and
   c. the interconnected floor space contains only Group A, Division 1 or 2, Group D, Group E, or Group F, Division 3 major occupancies.

2. **Applicant's Position**

The Applicant submitted that consideration should be given by the BCC to permit an interconnected floor space in this arena complex without the necessity of full compliance with interconnected floor space requirements of Articles 3.2.8.3. to 3.2.8.11. of the Building Code.

The Applicant submitted that an interconnected floor space is permitted for Group A, Division 1 & 2 occupancies in accordance with Sentence 3.2.8.2.(6) of the Building Code.

The Applicant submitted an analysis of occupant load, mobility of persons, fuel load and construction requirements to demonstrate that no greater hazard exists to occupants in this Group A, Division 3 arena by way of an interconnected floor space than would exist in a Group A, Division 1 or 2 occupancy where an interconnected floor space is permitted.

The Applicant also submitted that a revision included in the 1995 National Building Code permits Group A, Division 3 major occupancies to be contained in a building in which the first storey and the storey above it are interconnected.

3. **Chief Building Official's Position**

The Respondent submitted that an interconnected floor space is being proposed between level 1 and 2 in a Group A, Division 3 occupancy. The Building Code clearly does not permit an interconnected floor space in a Group A, Division 3 major occupancy without conforming to the requirements of Article 3.2.8.3. to 3.2.8.11.

The Respondent also submitted that the Applicant did not propose any additional measures to demonstrate sufficiency of compliance with the Building Code.

4. **Commission Ruling:**

It is the decision of the Building Code Commission that installing tempered glazing with sprinklers on one side of the glazing (on the second storey) provides sufficiency of compliance with the requirements of Sentence 3.2.8.2.(6) of the Building Code provided a fire safety plan is implemented to prohibit use of the second storey by the public when non-skating events are scheduled in the rinks of the ground floor of the building.

5. **Reasons:**
    6. Fire separations without fire resistance ratings are provided at the first floor level to act as a smoke barrier.
    7. The proposed separation at the second floor level provides increased time to evacuate the second floor level under fire conditions.
    8. The fire safety plan provides enhanced life safety.
    9. The 1995 National Building Code allows interconnected floor spaces in A-3 major occupancies.

Dated at Toronto, this 28th day, in the month of March, in the year 1996, for application number 1996-14.

RULING

1. **The Applicant**

   Mr. John Colussi, John Colussi and Associates Ltd. is an applicant for a building permit under the Building Code Act, 1992 to construct interior partitions, offices and washrooms at Westdale Enterprises, 351 Spinnaker Way, Unit No. 1, Concord, Ontario.

2. **Description of Constrution**

   The subject building is a fully sprinklered single storey structure facing two streets. It has a building area of 2,880 m? and contains four units. The building is classified as a Medium Hazard Industrial Occupancy (i.e. Group F, Division 2) under Article 3.2.2.51. of the Building Code.

   The Applicant occupies one of the four units (i.e. 1394 m?) in the building. The Applicant proposes to construct interior partitions, offices and washrooms.

3. **Dispute**

The dispute between the Applicant and Respondent concerns sufficiency of compliance with the technical requirements of Article 1.1.3.2. for the definition of a storage garage, Article 3.3.5.7. and Sentence 3.3.5.5.(4) of the Building Code. At issue is whether a building used to renovate mobile homes and trailers must comply with the fire separation and ventilation requirements for storage garages.

4. **Provision of the Building Code**

Article 1.1.3.2.Article 1.1.3.2. Definition of Storage Garages

Storage garage means a building or part there of intended for the storage or parking of motor vehicles and which contains no provision for the repair or servicing of such vehicles.

Article 3.3.5.7. Storage Garage Separation

A storage garage shall be separated from other occupancies by a fire separation with a fire-resistance rating of not less than 1.5 h

Sentence 3.3.5.5.(4) Repair and Storage Garages

Every garage shall be provided with natural or mechanical ventilation in conformance with the requirements of Subsection 6.2.2. to prevent excessive accumulation of carbon monoxide, exhaust fumes or flammable and toxic vapours.

5. **Applicant's Position**

The Applicant submitted that the use of the facility is to renovate mobile homes and trailers. The nature of the work is limited to the installation of upholstery, plumbing, air conditioning, and beds, seats and tables.

The Applicant submitted that there is absolutely no mechanical repairs done on the mobile homes or trailers, nor any type of painting. The Applicant submitted that the motor homes are driven in and parked. The majority of the motor homes do not have engines in them, they are totally stripped elsewhere and brought to this location for refurbishment.

6. **Chief Building Official's Position**

The Respondent submitted that a 1 1/2 hour fire separation is required between the office and the showroom in accordance with Article 3.3.5.7. of the Building Code. Furthermore, a mechanical ventilation system in accordance with Sentences 6.2.2.3.(1) and (4) is required in the storage garage. Sentence 6.2.2.3.(4) may not be applicable if the applicant can prove that the vehicles are not parked by mechanical means.

The Respondent submitted that since the operator of the business is not repairing any mechanical systems on the vehicles, the space was considered to be a storage garage rather than a repair garage.

7. **Commission Ruling:**

It is the decision of the Building Code Commission that the classification of the intended occupancy is Group F, Division 2 (i.e. Medium Hazard Industrial Occupancy), but by nature of the infrequent operation or movement of mobile homes is not considered as a storage nor repair garage and the requirements of Articles 3.3.5.7. and 3.3.5.5. of the Building Code do not apply.

8. **Reasons:**
   i. No mechanical repair or servicing is performed on the mobile homes.
   ii. No painting or body work will be carried out.
   iii. Movement of mobile homes in or out of the premises is very infrequent in the order of 2 to 3 per week and batteries are normally disconnected.
   iv. The occupant load is extremely low and by nature of the restoration time for the mobile homes a limited number of the public are present at any time.

Dated at Toronto, this 13th day, in the month of February, in the year 1996, for application number 1996-05.

RULING

1. **The Applicant**

   Mr. Bazz Van Willigen, Vice President is the holder of a permit under the Building Code Act, 1992 to construct a single family dwelling (i.e. house) at Lot 58, 83 Windrush Trail, Kitchener, Ontario.

2. **Description of Constrution**

   The subject building is a two storey single family dwelling (i.e. house). The stairs connecting the main floor and the second storey is the subject of the dispute.

   The stairs contain an intermediate portion (i.e. landing or large tread) between the floor levels where the stairs have a 45 degree change in direction. The Applicant contends that the stair is designed as a curved stair. The respondent states that the landing does not meet the requirements for landings.

3. **Dispute**

The dispute between the Applicant and Respondent concerns sufficiency of compliance with the technical requirements of Articles 9.8.4.1. 9.8.5.2. and 9.8.5.3. of the Building Code. At issue is whether the intermediate portion of the stair design is a landing or curved portion of the stair.

4. **Provision of the Building Code**

Article 9.8.4.1. Dimensions of Landings

Landings shall be at least as wide and as long as the width of stairs in which they occur, except that the length of landing for exterior stairs serving not more than 1 dwelling unit need not exceed 900 mm (2 ft 11 in), and the length of landing for all other stairs in a straight run need not exceed 1100 mm (3ft 7 in).

Article 9.8.5.2. Curved Stairs not in Exits

Except as permitted in Article 9.8.5.3., a curved stair not required as an exit shall have an average run of not less than 200 mm (77/8 in) and a minimum run of 150 mm (57/8 in) and shall have risers conforming to Article 9.8.3.1.

Article 9.8.5.3. Winders

1. Stairs within dwelling units may contain winders that converge to a centre point provided the winders turn through an angle of not more than 90§and individual treads turn through an angle of 30§.
2. Only one set of winders described in Sentence (1) shall be permitted between floor levels.

5. **Applicant's Position**

The Applicant submitted that the stairs comply with Article 9.8.5.2. of the Building Code. The Applicant submitted that the stair is designed as a curved stair and in no way compromises the intent of the Building Code or public safety. This stair has been used many times on a number of Monarch Construction sites.

6. **Chief Building Official's Position**

The Respondent submitted that the existing stair configuration does not meet the requirements for landings in Article 9.8.4.1. The landing length is not as wide as the width of the stairs, nor does it comply with the requirements of Article 9.8.2.1. for uniform treads and risers. The large intermediate portion is not uniform in its design for the entire run of the stairs.

The Respondent questioned the applicability of Article 9.8.5.2. for these stairs.

7. **Commission Ruling:**

   It is the decision of the Building Code Commission that the existing stair configuration provides sufficiency of compliance with Articles 9.8.4.1., 9.8.5.2. and 9.8.5.3. of the Building Code.

8. **Reason:**

   Information on past performance where the design has been used in Ontario indicates no adverse effect on safety with respect to movement up and down the stairs.

Dated at Toronto, this 13th day, in the month of February, in the year 1996, for application number 1996-04.

PLACE

Toronto, Ontario

DATE OF RULING

February 13th, 1996

RULING

1. **The Applicant**

   Mr. Peter Hryhorchuk, Plummer Memorial Public Hospital is an applicant for a permit under the Building Code Act, 1992 to construct a new exterior barrier free ramp that serves a newly enclosed secondary entrance to the Oncology Unit, 969 Queen Street East, Sault Ste. Marie, Ontario.

2. **Description of Constrution**

   The Applicant proposes to construct an 1100 mm wide exterior concrete side walk where the gradient of 1:17 requires the side walk to be considered a ramp. The grade adjacent to both sides of the ramp is 100 mm below the ramp surface.

3. **Dispute**

   The dispute between the Applicant and Respondent concerns sufficiency of compliance with the technical requirements of Clause 3.7.3.4.(1)(e) & (f) of the Building Code. At issue is whether the barrier free guard and handrail requirements for ramps need be applied to the access provided for patience visiting the Oncology Unit of Plummer Memorial Hospital.

4. **Provision of the Building Code**

   Clause 3.7.3.4.(1)(e) Ramps

   1. Ramps located in a barrier-free path of travel shall
      a. have a minimum width of 870 mm (2 ft 10 in) between handrails,
      b. have a maximum gradient of 1 in 12,
      c. have a level area of at least 1.5 m (4 ft 11 in) by 1.5 m (4 ft 11 in) at top and bottom of a ramp and where a door is located in a ramp, so that the level area extends at least 600 mm (23 5/8 in) beyond the latch side of the door opening, except that where the door opens away from the ramp, the area extending beyond the latch side of the door opening may be reduced to 300 mm (11 3/4 in),
      d. have a level area at least 1.5 m (4 ft 11 in) long and at least the same width as the ramp

i. at intervals of not more than 9 m (29 ft 6 in) along its length, and
ii. where there is an abrupt change in the direction of the ramp,

e. except as provided in Sentence (2), be equipped with handrails and guards on both sides conforming to Articles 3.4.6.4. and 3.4.6.5., and
f. be provided with a curb at least 50 mm (2 in) high on any side of the ramp where no solid enclosure or guard is provided.

5. **Applicant's Position**

The Applicant submitted that this is an exterior side walk in a landscaped area where the gradient 1:17 requires the ramp definition to apply. The grade adjacent to the ramp on both sides is within 100 mm of the ramp surface.

The Applicant submitted that the requirement under Clause 3.7.3.4.(1)(e) of the Building Code for a guard on an exterior barrier free ramp where no hazard exists, seems unnecessary.

The Applicant proposed to provide a 920 mm high handrail on both sides of the ramp in lieu of a 1070 mm high guard. The Applicant submitted that this arrangement meets the intent of the Barrier Free Access requirements.

6. **Chief Building Official's Position**

The Respondent submitted that there are two Building Code issues. The first is the matter of Clause 3.7.3.4.(1)(e) which requires a guard on both sides of the barrier free ramp regardless of the difference in elevation from the ramp surface to the adjacent ground. The second issue relates to the mounting height of the handrail and the minimum height of the guard. Sentence 3.7.3.4.(1)(e) requires the handrail and guard on the Barrier Free Ramp to conform to Articles 3.4.6.4. and 3.4.6.5. which requires the minimum height of the guard to be 1070 mm while the handrail cannot be higher than 920 mm.

7. **Commission Ruling:**

It is the decision of the Building Code Commission that the handrails on both sides of the ramp located at 920 mm in height designed as a guard provides sufficiency of compliance with Clause 3.7.3.4.(1)(e) & (f) of the Building Code.

8. **Reasons:**

i. A horizontal rail at not more than 50 mm above the ramp has been provided which would prevent the front wheels of a wheel chair from turning off the ramp.
ii. The differential elevation between the existing grade and the ramp is less than 100 mm.
iii. Providing a handrail at 920 mm is considered adequate for the intended purpose.

Dated at Toronto, this 13th day, in the month of February, in the year 1996, for application number 1996-03.

DATE OF RULING

January 24th, 1996

RULING

1. **The Applicant**

   Mr. David Rechtsman, Wild Oak Bay Home Corporation is the is the holder of a permit under the Building Code Act, 1992 to construct a greenhouse addition to an existing mercantile occupancy at 1400 O'Connor Drive, East York, Ontario.

2. **Description of Construction**

   The subject building is a 562 m greenhouse addition to an existing mercantile building.

   The existing building consists of a 1,161 m one storey masonry building with an unrated wood roof assembly supported on fire proofed structural steel. The existing building has undergone alterations and three additions were added to it totalling 929 m, t hus making the total building area (new and existing) 2090 m. Both the existing building and additions are protected by a supervised sprinkler system.

   The greenhouse is separated from the existing building by a 250 mm (10 inch) thick masonry wall. Access is provided from the existing building into the greenhouse. The construction of the greenhouse provides complete ease of egress from the greenhouse in the event of a fire. The greenhouse structure consists of steel non-fireproofed framing, 4 mm tempered glass roof and sides. The sides, when not used, will be closed by a rolled down canvas. The greenhouse is separated from the main building by a 250 m m (10 inch) thick concrete block wall. There are no permanent exterior nor interior walls in the greenhouse.

3. **Dispute**

   The dispute between the Applicant and Respondent concerns sufficiency of compliance with the technical requirements of Article 3.2.2.44. and Sentence

3.2.2.12.(1) of the Building Code. At issue is whether a sprinkler system is required in a greenhouse addition to an existing mercantile occupancy.

4. **Provisions of the Building Code**

Sentence 3.2.2.12.(1) Sprinklers in Lieu of Roof Rating

(1) The requirements in Articles 3.2.2.16. to 3.2.2.62. for roof assemblies to have a fire-resistance rating are permitted to be waived provided

(a) the building is sprinklered,

(b) the sprinkler system in Clause (a) is electrically supervised in conformance with sentence 3.2.4.16.(5), and

(c) the operation of the sprinkler system in Clause (a) will cause a signal to be transmitted to the fire department in conformance with Sentence 3.2.4.7.(3).

Article 3.2.2.44. Mercantile Buildings, up to 3 Storeys

(1) A building classified as Group E shall conform to Sentence (2) provided the building

(a) is not more than 3 storeys in building height, and

(b) has a building area not more than the value in Table 3.2.2.M.

(2) The building shall be of combustible or non-combustible construction used either singly or in combination, and

(a) floor assemblies shall be fire separations with a fire-resistance rating of not less than 45 min,

(b) mezzanines shall have, if of combustible construction, a fire-resistance rating of not less than 45 min,

(c) roof assemblies shall have a fire-resistance rating of not less than 45 min, except that in buildings not more than 1 storey in

building height, the fire-resistance rating is permitted to be waived provided the roof assembly is of non-combustible cons truction or is constructed as a fire-retardant treated wood roof system conforming to Article 3.1.14.1., and

(i) if unsprinklered, the building area is not more than 1 500 m2 (16,100 ft2), and

(ii) if sprinklered, the building area is not more than;

2 400 m2 (25,800 ft2) if facing 1 street, 3 000 m2 (32,300 ft2) if facing 2 streets, or
3 600 m2 (38,800 ft2) if facing 3 streets,

TABLE 3.2.2.M.

Forming Part of Sentence 3.2.2.44.(1)

No. of Storeys	Unsprinklered Maximum Area, m² (ft²)		
	Facing 1 Street	Facing 2 Streets	Facing 3 Streets
1	1 500 (16,100)	1 500 (16,100)	1 500 (16,000)
2	1 200 (12,900)	1 500 (16,100)	1 500 (16,100)
3	800 (8,610)	1000 (10,800)	1 200 (12, 900)
Sprinklered Maximum Area,m² (ft²)			
1	4 800 (51,700)	6 000 (64,600)	7 200 (77,500)
2	2 400 (25,800)	3 000 (32,300)	3 600 (38,800)
3	1 600 (17,200)	2 000 (21,500)	2 400 (25,800)
Column 1	2	3	4

(d) all loadbearing walls, columns and arches supporting an assembly required to have a fire-resistance rating shall have a fire

resistance rating of not less than 45 min or shall be of non-combustible construction, except that such members and assemblies supporting a fire separation shall have a fire-resistance rating not less than that required for the supported assembly.

5. **Applicant's Position**

The Applicant submitted that the requirement to sprinkler the greenhouse is excessive and should not be required in this instance for the following reasons:

1) The main building is of concrete block and steel construction and is fully sprinklered in compliance with the Building Code.

2) The greenhouse is accessory and subordinate to the Occupant's main use and the volume of people will be far less than in the main building.

3) The building/greenhouse arrangement was not contemplated when the subject Building Code regulation was being developed.

4) The purpose of the greenhouse is to provide an area of protective covering for plants and therefore the goods offered for sale to the public are non-combustible.

5) The greenhouse is separated from the building by a 10" concrete block wall.

6) The nature of the greenhouse construction allows complete ease of access/egress to the public in the event the need to exit the greenhouse should ever arise.

7) There is such a degree of sufficiency of compliance with the Building Code that sprinklering the greenhouse should not be a requirement in this instance.

6. **Chief Building Official's Position**

The Respondent submitted that Article 3.2.2.44. and Sentence 3.2.2.12.(1) require mercantile buildings in excess of 1500 m (16,100 ft) to be sprinklered and that the sprinkler system may be substituted in lieu of a fire rated roof assembly.

The Respondent submitted that the existing 1,161 m (12,500 ft) one storey, masonry building has an unrated wood roof assembly supported on structural steel fire proofed by sprayed-on fire proofing. The existing building has undergone alterations and three new additions were added to it totalling 929 m (10,000 ft)and making the total building area (new and existing) 2090 m (22,500 ft). Both the existing building and the additions are prot ected by a supervised sprinkler system.

The Respondent submitted that a permit was issued for a sprinklered 562 m (6,048 ft) greenhouse structure to be placed immediately to the west of the main building with its gables flashed against the main building.

The Respondent submitted that the Applicant does not wish to sprinkler the greenhouse structure.

7. Commission Ruling

It is the decision of the Building Code Commission that not providing sprinklering for the greenhouse provides sufficiency of compliance with the Building Code provided

a) an annual permit be obtained as required if the structure was temporary in nature, reconfirming its use for the display and sale of horticultural products; and

b) combustible storage be limited and considered as outdoor public storage under the Fire Code for exposure hazard.

It is also the decision of the Building Code Commission that the tempered glass used on the sloping roof does not provide sufficiency of compliance with the Building Code.

8. **Reasons:**

1) The unheated structure is used seasonally.

2) The structure is non-combustible construction.

3) The unenclosed greenhouse provides unlimited means of egress.

4) The existing building is sprinklered and is separated from the greenhouse by masonry walls.

5) Fire-spread through unprotected openings is addressed through the combustible storage provisions of the Fire Code.

6) The proposed structure of mercantile use is not a low human occupancy building as described in CAN/CGSB-12.20-M89 Structural Design of Glass for Buildings as referenced in Part 4 of the Building Code.

7) CAN/CGSB-12.20-M89 does not permit the use of tempered glass alone for sloped glazing and skylights since no restraining system is provided to prevent glass particles from falling in the event of glass breakage.

Dated at Toronto this **24th** day in the month of **January** in the year **1996** for application number **1995-67**

BCC Ruling No. 96-02-485

BUILDING CODE COMMISSION DECISION ON B.C.C. #96-02-485

IN THE MATTER OF Subsection 24(1) of the *Building Code Act, 1992.*

AND IN THE MATTER OF Subsection 9.8.8. of the Revised Regulation of Ontario 1990, Regulation 61, as amended by O.Regs. 400/91, 158/93, 160/93, 383/94 and 20/95 (the "Building Code").

AND IN THE MATTER OF an application by Mr. Stan Sukunda, Owner & Builder, for the resolution of a dispute with Mr. Harold Bratten, Chief Building Official, Borough of East York, concerning whether the height of the guard on the 2nd floor balcony; guard on top of the retaining wall and openings of the guard around interior stairwell provide sufficiency of compliance with Subsection 9.8.8. of the Building Code, at 55 Glenwood Crescent, East York, Ontario.

APPLICANT

Mr. Stan Sukunda
Concord, Ontario

RESPONDENT

Mr. Harold Bratten
Chief Building Official
Borough of East York

PANEL

Mr. Roy Philippe, Chair
Mr. Michael Lio
Ms. Susan Friedrich

PLACE

Toronto, Ontario

DATE OF RULING

January 24th, 1996

RULING

1. **The Applicant**

   Mr. Stan Sukunda, Owner & Builder is the recipient of an order to comply under the Building Code Act, 1992 requiring the guards on the 2nd floor balcony, front porch over the driveway and on top of the retaining wall to conform with the requirements of Subsection 9.8.8. of the Building Code at 55 Glenwood Crescent, East York, Ontario.

2. **Description of Constrution**

   The subject building is a single family dwelling (i.e. house). The height of guards on the second floor balcony and the front porch over the driveway are 990 mm (39 inches) high instead of 1070 mm (42 inches) as required, and the guards on top of the retaining walls vary from 500 mm (20 inches) to 736 mm (29 inches) instead of 900 mm (35 inches). The openings in guards around the stairwell are greater than the maximum 100 mm (4 inches) diameter.

3. **Dispute**

   The dispute between the Applicant and Respondent concerns sufficiency of compliance with the technical requirements of Subsection 9.8.8. of the Building Code. At issue is the height of the guard on the 2nd floor balcony; guard on top of retaining wall and the openings of the guard around interior stairwell.

4. **Provision of the Building Code**

   Subsection 9.8.8. Guards

   Subsection9.8.8.1. Required Guards

   1. Every exterior landing, porch, deck and every balcony, mezzanine, gallery, raised walkway and roof to which access is provided for other than for maintenance purposes, shall be protected by guards on all open sides where the difference in elevation between adjacent levels exceeds 600 mm (23 in).
   2. Every exterior stair with more than 6 risers shall be protected with guards on all open sides where the difference in elevation between the adjacent ground level and the stair exceeds 600 mm (23 in).

3. When an interior stair has more than 2 risers, the sides of the stair and the landing or floor level around the stair well shall be enclosed by walls or be protected by guards, except that a stair to an unfinished basement in a dwelling unit may have 1 unprotected side.

Subsection9.8.8.2. Height of Guards

4. Except as provided in Sentences (2) to (5), all guards, including those for balconies, shall be at least 1 070 mm (3 ft 6 in) high.
5. Guards for porches, decks, landings and balconies serving not more than one dwelling unit and which are not more than 1.8 m (5 ft 11 in) above the finished ground level are permitted to be a minimum of 900 mm (2 ft 11 in) high.
6. Except as provided in Sentence (4), guards for stairs shall be not less than 900 mm (2 ft 11 in) high measured vertically from a line drawn through the outside edges of the stair nosings, and 1 070 mm (3 ft 6 in) in height at landings.
7. Guards for stairs within dwelling units and stairs serving not more than one dwelling unit shall be not less 800 mm (2 ft 7 in) measured vertically above a line drawn through the outside edges of stair nosings, and not less than 900 mm (2 ft 11 in) above landings.
8. All required guards within dwelling units other than those described in Sentence (4) shall be not less than 900 mm (2 ft 11 in) high.

Subsection9.8.8.3. Guards for Floors and Ramps in Garages

Except for floors of garages referred in Section 9.35, a continuous curb not less than 150 mm (5 in) in height and a guard not less than 1 070 mm (3 ft 6 in) above the floor level shall be provided at every opening through a garage floor and around the perimeter of such floor and ramps where the exterior walls are omitted and where the top floor is 600 mm (23 in) or more above an adjacent ground or floor level.

Subsection9.8.8.4. Openings in Guards

Openings through a guard on balconies, porches, and decks, an exit stair, or stairs, landings and the floor level around a stairwell in a dwelling unit, shall be of a size so as to prevent the passage of a spherical object having diameter of 100 mm (4 in) in residential occupancies and 200 mm (7 in) in other occupancies, unless it can be shown that the location and size of such openings which exceed theses limits do not represent a hazard.

Subsection9.8.8.5. Design to Prevent Climbing

Guards around exterior balconies, porches, and decks of buildings of residential occupancy shall be designed so that no member, attachment or opening located between 100 mm (4 in) and 900 mm (2 ft 11 in) above the floor of the balcony, porch or deck will facilitate climbing.

Subsection9.8.8.6. Guards for ramps

Guards for ramps including vehicular ramps shall conform to the requirements for guards for stairs in Article 9.8.8.2. and 9.8.8.4.

5. **Applicant's Position**

The Applicant submitted that the balcony guard on the second floor is the shape of a half moon and that there is no way the same shape could be maintained if the guard height is increased.

The Applicant submitted that he agreed to increase the height of the guard over the garage, but felt the height of the guard on the retaining wall which varies from 500 mm (20 inches) to 736 mm (29 inches) is high enough to prevent someone from falling.

The Applicant also submitted that the openings of the guard around the interior stair well are 3 inches between the square portion of the spindles and 4 ¬ inches between the round part of the spindles.

6. **Chief Building Official's Position**

The Respondent submitted that the second floor exterior balcony and the first floor guard over the garage measures 990 mm (3ft. 3 in.) above the floor rather than the requisite 1070 mm (3 ft. 6 in.).

The Respondent submitted that the spindles in the interior second floor guard are spaced up to 4 inches apart rather than the required 100 mm (4 inches).

The Respondent also submitted that the guards on top of the retaining wall beside the driveway range from 20 inches to 29 inches in height instead of the required 35 inches (900 mm).

7. **Commission Ruling:**

It is the decision of the Building Code Commission that:

a. Openings in the guard rail around the interior stairwell in excess of 100 mm do not provide sufficiency of compliance with Article 9.8.8.4. of the Building Code.
b. The height of the guard rail on the 2nd floor exterior balcony less than 1070 mm does not provide sufficiency of compliance with the Building Code.
c. The height of the guard rails on top of the retaining wall where less than 1070 mm does not provide sufficiency of compliance with the Building Code where the height of the retaining wall exceeds 1 metre as identified in Articles 4.4.3.1. and 2.1.2.1. of the Building Code.

8. **Reason:**

The guard height and openings through guards do not comply with the Building Code and no alternatives were provided to consider sufficiency of compliance.

Dated at Toronto, this 24th day, in the month of January, in the year 1996, for application number 1996-01.

BCC Ruling No. 96-01-484

BUILDING CODE COMMISSION DECISION ON B.C.C. #96-01-484

IN THE MATTER OF Subsection 24(1) of the *Building Code Act, 1992.*

AND IN THE MATTER OF Sentence 9.10.14.12.(2) of the Revised Regulation of Ontario 1990, Regulation 61, as amended by O.Regs. 400/91, 158/93, 160/93, 383/94 and 20/95 (the "Building Code").

AND IN THE MATTER OF an application by Mr. Malcolm B. Thomas, Homeowner, for the resolution of a dispute with Mr. Harold Bratten, Chief Building Official, Borough of East York, concerning whether applying an intumescent fire retardant paint to combustible cladding on an existing north exposing building face will provide sufficiency of compliance with the requirements for non-combustible cladding in Sentence 9.10.14.12.(2) of the Building Code, at 10 Rutherglen Road, Toronto, Ontario.

APPLICANT

Mr. Malcolm B. Thomas
Toronto, Ontario

RESPONDENT

Mr. Harold Bratten
Chief Building Official
Borough of East York

PANEL

Mr. Roy Philippe, Chair
Mr. Michael Lio
Ms. Susan Friedrich

PLACE

Toronto, Ontario

DATE OF RULING

January 24th, 1996

RULING

1. **The Applicant**

   Mr. Malcolm B. Thomas, Homeowner is the holder of a permit under the Building Code Act, 1992 to construct a second storey addition to a single family dwelling at 10 Rutherglen Road, Toronto, Ontario.

2. **Description of Constrution**

   The subject building is a second storey wood frame addition to a single family dwelling that is located approximately 450 mm (1' 6") from the property line.

   The existing first storey cladding consists of brick veneer. The exposing building face on the new second storey is clad with 7/16" Abitibi stucco board with 3/4"x 4"x 6" and 8" battens over the joints.

   The construction of the exposing building face has the required fire resistance rating, but does not have noncombustible cladding.

3. **Dispute**

   The dispute between the Applicant and Respondent concerns sufficiency of compliance with the technical requirements of Sentence 9.10.14.12.(2) of the Building Code. At issue is whether applying an intumescent fire retardant paint to combustible cladding on the second storey exposing building face will provide sufficiency of compliance with the requirement for noncombustible cladding.

4. **Provision of the Building Code**

   Sentence 9.10.14.12.(2) Exposing Building Face of Houses

   2. Except as required in Article 9.10.14.3., in buildings containing only dwelling units in which there is no dwelling unit above another dwelling unit the requirements of Article 9.10.14.11. do not apply provided that the exposing building face has a fire-resistance rating of not less than 45 minutes where the limiting distance is less than 1.2 m (3 ft 11

in) and when the limiting distance is less than 0.6 m (23 5/8"in), the exposing building face is clad with noncombustible material.

5. **Applicant's Position**

The Applicant submitted that the construction of subject exposing building face has the required fire resistance rating, but does not have noncombustible cladding.

The Applicant proposed to paint the exterior of the second storey with intumescent fire retardant paint.

The Applicant submitted that the requirement for noncombustible cladding was unknown to him until five weeks after the start of construction and about eight weeks after the permit was issued. If the municipality would have advised him of this when the permit was issued he would not have spent part of the construction budget on the wrong material. The Applicant estimated that it would cost about $3000.00 to rectify the situation.

The Applicant submitted that the regulation should be based on the distance between neighbouring buildings and not the distance from the lot line. The north exposing building face is separated from the building on the adjacent property by approximately 3 m.

6. **Chief Building Official's Position**

The Respondent submitted that he does not have the authority under the Building Code Act to accept the combustible cladding consisting of stucco board.

Sentence 9.10.14.12.(2) of the Building Code clearly requires the north exposing building space to be clad with noncombustible material.

7. **Commission Ruling:**

It is the decision of the Building Code Commission that applying intumescent fire retardant paint to combustible cladding on the north exposing building face of the second floor addition in combination with other site specific safety provisions demonstrates sufficiency of compliance with the Building Code.

8. **Reasons:**

b. The building is in close proximity to a fire station.

c. The building is separated from the adjacent building by a distance of approximately 3.92 m (9' 7").
d. The building is located 457 mm (18") from the property line.
e. Evidence was submitted describing the intumescent paint product, including surface preparation and application.
f. No evidence was provided to suggest that the application of intumescent paint alone to a combustible material would change its characteristics to meet the definition of a non-combustible material in accordance with the Building Code.
g. The general use of intumescent paint as a means of complying with the cladding requirements of the spatial separation provisions of the Building Code should be referred to the Building Materials Evaluation Commission for consideration.

Dated at Toronto, this 24th day, in the month of January, in the year 1996, for application number 1995-65.

DATE OF RULING

December 21st, 1995

RULING

1. **The Applicant**

   Mr. David Cole, Helmer Stranks Cole Architects Inc. is the recipient of an order to comply under the Building Code Act, 1992 to provide a listed fire pump and controller for the standpipe and hose system being installed at the Conservation Co-op, Ottawa, Ontario.

2. **Description of Constrution**

   he subject building is a 4 storey residential occupancy with a building area of 2260 m².

   The Applicant is proposing to install an unlisted fire pump on the west wing basement service corridor of the building. The fire pump has a required discharge pressure of less than 280 kpa (40.6 psig).

3. **Dispute**

   The dispute between the Applicant and Respondent concerns an interpretation of the technical requirements of Sentence 3.2.9.3.(1) and 3.2.9.3.(7) of the Building Code. At issue is the determination of the term discharge pressure in Sentence 3.2.9.3.(7).

4. **Provision of the Building Code**

   Sentence 3.2.9.3.(1) & (7) Standpipe and Hose System Design

   1. Except as provided in Sentences (2) to (10), and Articles 3.2.9.4. to 3.2.9.7., where standpipe and hose systems are required, the design, construction, installation and testing of such standpipe and hose systems shall be in conformance with NFPA 14, "Installation of Standpipe and Hose Systems".

   7. Pumps required to have a discharge pressure greater than 280 kPa (40.6 psi) (gauge) and their controllers shall be listed and labelled.

5. **Applicant's Position**

   The Applicant submitted that Sentence 3.2.9.3.(7) states that "Pumps required to have a discharge pressure greater than 280 kpa (40.6 psi) gauge and their controllers shall be listed and labelled.

The Applicant submitted that it is their understanding that this clause exists because UL/ULC only commence listing of fire pumps at 40 psi. Similarly NFPA 20 Centrifugal Fire Pumps only rates pump capacities from 40 psi.

The Applicant submitted that the Respondent is confusing the "pump discharge pressure" with the "system discharge pressure". The Applicant submitted that the discharge of the pump, when installed, will be higher than 40 psi. It must in fact be higher than 65 psi in order to deliver 65 psi to the fire hose cabinets. If this was the correct interpretation of "pump discharge pressure" then Clause 3.2.9.3.(7) of the Building Code is superfluous as all fire pumps would have to operate with a discharge pressure higher than 65 psi (including jockey pumps).There would also be no reason for ULC to commence listing of fire pumps at 40 psi.

The Applicant submitted that the "pump discharge pressure" refers to the pump performance only i.e. how much pressure the pump must provide to deliver 65 psi to the fire hose cabinets.

6. **Chief Building Official's Position**

The Respondent submitted that in accordance with Sentence 3.2.9.3.(7) of the Building Code, a fire pump registering a discharge pressure greater than 280 kpa (40.6 psi) gauge, must be listed. The discharge pressure indicated on the gauge of the installed pump ranges from 60 psi (City pressure) to 95 psi (pump running). Therefore, the fire pump and its controller must be listed and labelled for this use.

7. **Commission Ruling:**

t is the interpretation of the Building Code Commission that the discharge pressure in Sentence 3.2.9.3.(7) refers to differential rated pressure (i.e. difference between suction and discharge pressure of the pump) and if such value exceeds 40.6 psig determined through hydraulic calculations on the system reflecting the municipal water supply pressure the pump and controllers shall be listed and labelled.

Dated at Toronto, this 21st day, in the month of December, in the year 1995, for application number 1995-68.

For the Respondent

RULING

1. **The Applicant**

   Mr. George Chelwick, Project Manager, Casino Windsor Limited is an applicant for a permit under the Building Code Act, 1992 to construct a four storey parking garage with two basement levels and one occupiable roof for the Windsor Casino, Windsor, Ontario.

2. **Description of Constrution**

   The subject building is a free standing parking garage for the Windsor Casino. The building is four storeys in building height, with two basement levels and one occupiable roof. The building area is approximately 14,000 m² on all levels except the fourth storey and roof which has an area of approximately 10,800 m². As the building area is 14,000 m², the building cannot be classified to Article 3.2.2.60. nor 3.2.2.61. It is required to be constructed to Article 3.2.2.62.

   The height of the building, measured from the roof is approximately 12.8 m. The building will be constructed of non combustible materials.

   The above grade portion of the building is open air such that at least 25 percent of the building perimeter walls are open to the exterior. All four streets about the perimeter of the building can be used as fire routes.

   The above grade sprinkler system is voluntary. The building is equipped with a fire alarm system.

3. **Dispute**

The dispute between the Applicant and Respondent concerns sufficiency of compliance with the technical requirements of Sentence 3.2.9.1.(1) of the Building Code. At issue is whether the voluntary sprinkler system and the building configuration provides sufficiency of compliance in lieu of the standpipe and hose system requirements.

4. **Provision of the Building Code**

Sentence 3.2.9.2.(1) Exceptions to the Requirement for Standpipe and Hose Systems

A standpipe need not be installed in a storage garage conforming to Article 3.2.2.60. provided the building is not more than 15 m high.

5. **Applicant's Position**

The Applicant submitted that sufficiency of compliance with the standpipe and hose system has been achieved by the following:

- The Building Code waives the standpipe and hose system in an open air parking garage conforming to Article 3.2.2.60. provided the building is not more than 15 m high. This Article limits the building area to 10,000 m², regardless of sprinkler protection. This is the only section in the Building Code where sprinkler protection is not recognized as a method of doubling the building area when classifying a building to the requirements of Section 3.2.2.

  Article 3.2.2.60. "Industrial Buildings, Division 3, Storage Garages up to 22 m High" requires the garage to be constructed as follows:

  - noncombustible construction
  - not more than 22 m measured from grade to the ceiling level of the top storey,
  - not more than 10,000 m² in building area, and
  - all areas of the building be within 60 m of an exterior wall opening.

  This Article does not recognize the benefits of sprinklers. All other building types (including high hazard occupancies), permit the building area to be doubled. In review of this Article with the National Research Council and the Housing Development and

Buildings Branch, there is no record as to why sprinkler protection on this type of building was not considered.

The parking garage has an area of 14,000 m². The height of the building is approximately 12.8 m when measured from the roof to grade. Therefore the proposed garage would comply with Article 3.2.3.60. where sprinkler protection is recognized as a method of doubling building area.

- The building is equipped with fire department access routes that are superior to those required by the Building Code. The building is only required to face one street such that the principal entrance be within 15 m of the fire route. All four sides of the building are within 15 m of a fire route. Should the fire department be required to use fire hoses, the department is not limited to a particular building facade.
- The garage is considered "open air" as at least 25 percent of the building perimeter is open to the exterior. For nonsprinklered buildings, the Building Code in Sentence 3.2.5.1.(1) requires that access openings be provided every 15 m of wall in each wall required to face a street in Subsection 3.2.2.

  Fire department access to all floors exceeds the access opening requirements. All floors and all building faces have unlimited access openings.

- The building Code does not require the open air floors to be rated in a building subject to the construction requirements of Article 3.2.2.60. The above grade floors of the parking garage will be designed to achieve a rating of at least 1 hour.
- The open air configuration allows the fire fighters unlimited methods of approach, from any direction, without the boundary layer of heat and smoke impacting on their fire fighting procedures. The smoke will vent to the exterior on the side of the building.
- The Life Safety Code (NFPA 101) does not require a standpipe and hose system in an open air garage.
- The Building Code waives the standpipe system in sprinklered buildings up to 3 storeys in building height or 14 m in height measured between grade and the upper most storey. There is no limitation to the building area and the building need not be open air. As such it is possible to construct a fully enclosed 3 storey building with an unlimited area, without a standpipe system.

The free standing Windsor Casino parking garage is open air and faces four streets for purposes of fire department access. The parking garage is less than 14 m high, yet is 4 storeys in building height.

- **Chief Building Official's Position**

The Respondent submitted that he cannot concur or accept the Applicant's proposal. Sentence 3.2.9.1.(1) of the Building Code states that "a standpipe and hose system shall be installed in every building that is more than 3 storeys in building height". The proposed storage garage exceeds three storeys. The exemption of the standpipe and hose system in Sentence 3.2.9.2.(1) is not applicable in this case as the storage garage does not fall under Article 3.2.2.60. of the Building Code for open air storage garages.

- **Commission Ruling:**

It is the decision of the Building Code Commission that the provision of a voluntary sprinkler system to N.F.P.A. 13 provides sufficiency of compliance with Article 3.2.9.1. of the Building Code for standpipe and hose systems in storeys at and below grade.

- **Reasons:**

1. The building has a voluntary sprinkler system.
2. The building is accessible from 4 streets with fire department access openings at all levels above grade.
3. The building is used as an open air parking garage.
4. The building exceeds the floor area requirements but is within the height requirements for the standpipe and hose system exception in Sentence 3.2.9.2.(1) of the Building Code.
5. Security and monitoring system are being included as part of the Casino operations.
6. The Life Safety Code (N.F.P.A. 101) does not require a standpipe and hose system in an open air parking garage.

For the Respondent

RULING

1. **The Applicant**

   Mr. John Tomkin, Bracebridge Camping & Trailer Park is the holder of a permit under the Building Code Act, 1992 to construct a public pool at the Bracebridge Camping & Trailer Park, Bracebridge, Ontario.

2. **Description of Constrution**

   The subject public pool is a Class B pool with a water volume of 26,500 US gallons (102025 litres). It is provided with a Hayward circulation kit consisting of a 24 inch sand filter and a 1« HP pump.

   The public pool has a constant water depth of 4 feet (1.22 m) and is provided with only one main drain. The circulation system flow rate is more than 3 l/s.

   The pool is completely installed, backfilled, raked and ready for sod or grass seed.

3. **Dispute**

The dispute between the Applicant and Respondent concerns sufficiency of compliance with the technical requirements of Sentence 3.11.8.1.(15) of the Building Code. The Applicant proposes to reduce the flow rate of the recirculation system to 3 l/s when the pool is being used and then increase the flow rate to three times the pool volume in 24 hours in lieu of providing two or more drains.

4. **Provision of the Building Code**

Sentence 3.11.8.1.(15) Recirculation and Vacuum Systems

15. Except as provided in Sentence 3.11.6.1.(7) for a modified pool, where a public pool has a recirculation system flow rate of more than 3 l/s (0.66 gal/s), the pool shall
    a. be provided with two or more main drains separated by not less than 1.2 m (3 ft 11 in), and
    b. be capable of being emptied through the drains in twelve hours or less.

5. **Applicant's Position**

The Applicant proposed to reduce the flow rate to meet the maximum permitted rate of 3 l/s during the day when the pool is in use, and increase the flow to a maximum of 4 l/s during off-time use.

The Applicant submitted that the flow rate of 3 l/s for 11 hours and 4 l/s for 13 hours would result in the volume of water in the pool being exchanged three times during a 24 hour period, which is required by the Building Code.

The Applicant submitted that this proposal would address the potential danger of someone's hair or other portion of their body being sucked into the main drain causing bodily harm.

The Applicant provided calculations showing the amount of water filtered over various times at various rates. The sum total of the maximum flow rate for 11 hours and the maximum flow rate for 13 hours is within a few litres of the volume of the pool, 102,025 litres by three.

6. **Chief Building Officials Position**

The Respondent submitted that the public pool has been constructed with only one main drain and the recirculation system flow rate is more than 3 l/s. It is approximately 3.5 l/s.

The Respondent submitted that he cannot accept the proposal submitted by the Applicant because it does not comply with Sentence 3.11.8.1.(15) of the Building Code. The reduction of the flow rate by moving valves and observing the flow meter appears to allow a great deal of human error where life safety is concerned.

7. **Commission Ruling:**

It is the decision of the Building Code Commission that reducing the flow rates during operating hours to 3 l/s and increasing the flow rate during periods when the pool is closed and secured to approximately 4 l/s does not provide sufficiency of compliance with Sentence 3.11.8.1.(15) of the Building Code.

8. **Reasons:**

15. Unattended use may occur during off hours when velocities in excess of the Building Code requirements for main drains are present.
16. Acceptance of a reduced flow to 3 l/s does not satisfy the recirculation system requirements of Sentence 3.11.8.1.(5) of the Building Code.
17. Proposed Building Code amendments by the Public Pool Task Force exceed present Building Code values as noted below:
    i. Sentence 3.11.8.1.(5) - Increase the turnover for a Class B pool from 3 to 4 times the pool's water volume every 24 hours (from 8 to 6 hours).
    ii. Sentence 3.11.8.1.(15) - Eliminate one main drain requirement for a recirculation system of 3 l/s, so each public pool has to be provided with at least 2 main drains.

Dated at Toronto, this 21th day, in the month of December, in the year 1995, for application number 1995-66.

Dunleavy Cordum Associates Inc.
Markham, Ontario
As Applicant

RULING

1. **The Applicant**

   Mr. Mel Hinde, Dunleavy Cordun Associates Inc. is an applicant for a permit under the Building Code Act, 1992 to install two semi- recessed barrier free vanity mounted lavatories in the ground floor public washrooms in Tower "C" Place De Ville, 330 Sparks Street, Ottawa, Ontario.

2. **Description of Constrution**

   The public washroom on the ground floor of Tower "C" Place De Ville were provided with two semi-recessed barrier free vanity mounted lavatories.

   A clearance of 680-690 mm has been provided beneath the bottom of the lavatories and 240-245 mm in the front, whereas, the Building Code requires 710 mm and 260 mm respectively.

3. **Dispute**

   The dispute between the Applicant and Respondent concerns sufficiency of compliance with the technical requirements of Article 3.7.3.10. of the Building Code. At issue is whether the two semi-recessed, vanity mounted lavatories installed in the barrier free washroom provides sufficiency of compliance with the Building Code.

4. **Provision of the Building Code**

   Article 3.7.3.10. Lavatories

   1. Barrier-free washrooms shall
      a. be provided with a lavatory which shall

i. be located so that the distance between the centreline of the fixture and the side wall is not less than 460 mm (18 in),
ii. have a clearance of at least 710 mm (2 ft 4 in) beneath the bottom of the lavatory to a point at least 260 mm (10¬ in) in from the front,
iii. have insulated waste outlet and hot water supply pipes to prevent burns or have water supply temperature limited to a maximum of 43§C (109§F),
iv. have faucet handles of the lever type that are not spring-loaded, and are located so that the distance from the centreline of the faucet to the edge of the basin or, where the basin is mounted in a vanity, to the front edge of the vanity, is not more than 485 mm (19 in),
v. have no shelves or other projections located above it so as to create a hazard, and
vi. be mounted so that the top of the lavatory or, where the lavatory is in a vanity, the top of the vanity is not more than 840 mm (2 ft 9 in) above the finished floor,

b. have soap and towel dispensers that are
i. located to be accessible to persons in wheelchairs and so that the dispensing height is not more than 1 200 mm (3 ft 11 in) above the floor, and
ii. operable with a single hand, and

c. have dispensing or hand-operated washroom accessories, except those located in toilet stalls or described in Clauses (a) or (b), mounted so that the dispensing height is between 900 mm (2 ft 11 in) and 1 200 mm (3 ft 11 in) above the floor.

5. **Applicant's Position**

The Applicant submitted that the two dimensions of the semi- recessed lavatory, from finished floor to the underside of the lavatory and from the front edge of the vanity fascia to the front edge of the lavatory, differ from the dimensions stated in the Building Code by 20 mm and 15 mm respectively. The lavatory, however, has been tested and conforms to C.S.A. Standards for barrier free as well as National Building Code Standards. The unit is on display in Access Place in Toronto and has been specified and installed in many projects throughout the Province.

The Applicant submitted that since the lavatory conforms to the National Building Code and C.S.A. Standards, and meets all other Building Code requirements for barrier free, it should be permitted to remain installed at this location and be deemed as barrier free.

6. **Chief Building Officials Position**

   The Respondent submitted that the two lavatories have been installed with clearances less than that required by Subclause 3.7.3.10(1)(a)(iii) of the Building Code. A clearance of 680-690 mm has been provided beneath the bottom of the lavatories and 240- 245 mm, measured in from the front, whereas, the Building Code requires 710 mm and 260 mm respectively.

   The Respondent submitted that the Industry continues to use barrier-free lavatories that are identified as meeting both the C.S.A. Standards and the National Building Code, but, fail to comply with the Building Code Regulations. These regulations are very clear with respect to the required clearances due to the sensitivity of barrier-free design, consistent enforcement of the regulations is important.

   The Respondent submitted that although he is sympathetic to the problem, he does not have the authority to accept a deviation from the prescriptive requirements of the Building Code.

7. **Commission Ruling:**

   It is the decision of the Building Code Commission that the two semi-recessed vanity mounted lavatories installed in a barrier free washroom do not comply with Article 3.7.3.10. of the Building Code.

8. **Reasons:**
   1. According to product literature the lavatory fails to meet one or both of the Building Code requirements for a clearance of at least 710 mm beneath the bottom and a height from the top of the lavatory to finished floor of no more than 840 mm.
   2. The Applicant was unable to demonstrate sufficiency of compliance with the Building Code.

Dated at Toronto, this 12th day, in the month of December, in the year 1995, for application number 1995-57.

RULING

1. **The Applicant**

   Mr. Ted Batcher, Batcher, Wasserman Barrister, Solicitor & Notaries is the holder of a permit under the Building Code Act, 1992 to renovate an existing three storey building to accommodate a retail store and five dwelling units at 266 Christie Street, Toronto, Ontario.

2. **Description of Constrution**

   The Applicant proposes to convert an existing three storey building from a laundry shop with four dwelling units to a retail store with five dwelling units.

   The north exposing building face has a limiting distance of 0.25 m (10 inches).

3. **Dispute**

   The dispute between the Applicant and Respondent concerns sufficiency of compliance with the technical requirements of Articles 9.7.1.2., 9.32.2.1. and 9.10.14.1. and Part 11 (Required Light

and Ventilation) of the Building Code. At issue is whether: i) residential occupancies conform to the light and ventilation requirements; and, ii) the north exposing building face complies with the spatial separation provisions in the Building Code, at 266 Christie Street, Toronto, Ontario.

4. **Provision of the Building Code**

Article 9.7.1.2. Minimum Window Areas

1. Except as required in Article 9.7.1.3., the minimum window glass area for rooms in buildings of residential occupancy or which are used for sleeping shall conform to Table 9.7.1.A.
2. The unobstructed glass area of a door or skylight is considered equivalent to that of a window.

Article 9.10.14.1. Maximum Percentage of Unprotected Openings

3. Except as provided in Sentence (2) and in Articles 9.10.14.3. to 9.10.14.11., the maximum percentage of unprotected openings in an exposing building face shall conform to Table 9.10.14.A. or to Subsection 3.2.3., whichever is the least restrictive for the occupancy being considered.
4. An opening in an exposing building face not more than 130 cm^2 (20 in^2) shall not be considered an unprotected opening.

Article 9.32.2.1. Natural Ventilation Area

5. The unobstructed openable ventilation area to the outdoors for rooms and spaces in residential buildings ventilated by natural means shall conform to Table 9.32.2.A.
6. Where a vestibule opens directly off a living or dining room within a dwelling unit, ventilation to the outdoors for such rooms may be through the vestibule.

Part 11 C93

g. Where windows are not used as a means of egress and where they do not conflict with ventilation requirements, the minimum glass areas as shown in Table 9.7.1.A. may be reduced by 50%, and
h. an existing room converted to an interior room created by an addition shall not require a window, provided there is an opening in a dividing wall to an adjoining room where the

adjoining room has a minimum of 5% window area of the combined floor areas, and provided the required ventilation for the combined room is maintained.

5. **Applicant's Position**

The Applicant submitted that the building has been renovated to include a retail store and five dwelling units. Openings were provided in the north side of building to permit ventilation and some light in accordance with the Building Code.

It is the Applicant's opinion that the building complies with the Building Code with respect to the light, ventilation and spatial separation requirements.

6. **Chief Building Official's Position**

The Respondent submitted that with the exception of the second floor bedrooms at the east and west ends of the building, the rooms in the residential occupancies do not conform with the light and ventilation requirements of the Building Code. The third floor dwelling units have similar problems, but roof skylights are proposed.

The Respondent submitted that the proposed window openings open onto a balcony which is recessed into the north exposing building face. The north wall has a limiting distance of 0.25m. (10 in.)

The Respondent also submitted that in the event of a fire, flames from the recessed areas could be directed onto an adjacent building built at the property line. Also, a building constructed at the north property line would certainly block off the already poor lighting and ventilation provided at the balconies. He also added that the Applicant was advised that unprotected openings were not permitted in the north and south walls.

7. **Commission Ruling:**

It is the decision of the Building Code Commission that providing unobstructed glass areas in doors in the recessed balconies and skylights at the third floor level provide sufficiency of compliance with Articles 9.7.1.2., 9.32.2.1 and 9.10.14.1. provided the glass area meets the total area as outlined in Table 9.7.1.A. of the Building Code.

8. **Reasons:**
    0. Glazing which has been proposed will be installed more than 1.2 m from the property line and does not project towards the property line.

1. Proposed unobstructed openable areas meet minimum requirements for natural ventilation.
2. Proposed windows meet minimum area requirements.
3. A limited number of suites are affected.

Dated at Toronto, this 5th day, in the month of December, in the year 1995, for application number 1995-44.

The Respondent

RULING

1. **The Applicant**

   Ms. Jill Moir, Grey Condominium Corporation No. 18, Collingwood is the holder of permit under the Building Code Act, 1992 for remedial work to five existing 3-Storey residential buildings, at "Chateau Ridge Condominium, Grey Condominium Corporation No. 18, Collingwood, Ontario.

2. **Description of Constrution**

   The five buildings were constructed in 1986-1987 and occupied soon after construction was completed. The Condominium Corporation authorized an independent consulting engineering firm to inspect and report on the condition of the five new buildings with respect to the Building Code after construction was completed.

   In January 1995 the Condominium Corporation retained the services of the same firm to inspect and evaluate the five buildings in terms of the life safety retrofit legislation in Section 9.5 of the Ontario Fire Code (O. Reg 627/92). The consultant's findings indicate deficiencies with respect

to the retrofit legislation and the Building Code applicable (1983) at the time of original construction.

The following applies to the subject buildings:

- Three storey building height
- Two storey dwelling units located above one another
- Building area: Block A - 499 sq m
- Block B - 499 sq m
- Block C - 399 sq m
- Block D - 584 sq m
- Block E - 300 sq m/399 sq m (divided by firewall).
- Mixed combustible and noncombustible construction
- Smoke alarm in each unit
- Total of 54 dwelling units
- Eight unit models (ie., A, A1, B, B1, AE, A1E, C and C1)
- Managed by Blue Mountain Resorts and made available to the public on nightly, week-end and weekly basis.

The following construction is proposed for the subject buildings:

- Install a fire alarm and detection system rather than providing a second and separate exit for second storey dwelling units that share an interior stair. Install a fire alarm and detection system rather than providing a third storey exterior balcony for Unit A1E.
- Replace the fire door and frame to the maid's closet that opens into the interior exit stair rather than relocate the hydro circuit panel and eliminate closet. Thermal detection will also be installed in the closet.
- Protect unprotected stair window, exposed to unprotected suite window with wired glass in hardwood frame rather than a steel frame.

3. **Dispute**

The dispute between the Applicant and Respondent concerns sufficiency of compliance with the technical requirements of Articles 9.9.9.3, 9.9.2.6. & 9.9.4.5. and Sentence 9.9.9.1.(3) of the Building Code. At issue is whether the proposed renovations to improve the egress conditions in five existing 3-storey residential buildings will provide sufficiency of compliance with the Building Code.

4. **Provision of the Building Code**

Article 9.9.9.3. Shared Egress Facilities

1. A dwelling unit shall be provided with a second and separate means of egress where an egress door from the dwelling unit opens onto
    a. an exit stairway serving more than 1 suite,
    b. a public corridor serving more than one suite served by a single exit stairway,
    c. an exterior passageway serving more than one suite and served by a single exit stairway, or
    d. a balcony serving more than one suite and served by a single exit stairway.

Article 9.9.2.6. Ancillary Rooms

Ancillary rooms such as storage rooms, washrooms, toilet rooms, laundry rooms and service rooms shall not open directly into an exit.

Article 9.9.4.5. Openings in Exterior Walls of Exits

Openings in the exterior wall of an exit shall be protected with wired glass or glass block installed in accordance with Articles 9.10.13.5. and 9.10.13.7., where openings may be exposed to the hazard of a fire in another fire compartment of the same building.

Sentence 9.9.9.1.(3) Travel Unit to Exits or Egress Doors

- The travel limit from a floor level in a dwelling unit to an exit or egress door may exceed 1 storey where that floor level has direct access to a balcony.

5. **Applicant's Position**

The Applicant submitted that the Permit application has been made for proposed construction that will improve the level of fire safety in the existing buildings.

The Applicant submitted that the 1983 edition of the Building Code was in force at the time of the original permit. Although the requirements have not changed, the references have.

The Applicant submitted the following information concerning the matter in dispute:

i. Article 9.9.9.3. Shared Egress Facility

The Applicant submitted that second storey units A1, B1 and C1 have an entrance door into a shared interior exit stair. These units do not have a separate and second means of egress. Units A1 and C1 have an exterior balcony on the second storey, however, this condition does not comply with Article 9.9.9.3. of the Building Code.

Since it is not feasible to provide a second exit for the second storey units, a ULC listed fire alarm and detection system will be installed in accordance with CAN/ULC - S524 - M, "Standard for the Installation of Fire Alarm Systems". This will not be a Building Code conforming fire alarm system requiring manual pull stations. Rather, the proposed system is a measure to compensate for egress deficiencies:

- Single-stage, single-zone fire alarm control equipment in a location best suited for responding resort staff and fire department (e.g., linen closet nearest access route).
- Fire alarm system for each of the five buildings will be monitored at the Blue Mountain Resort switchboard.
- Rate of rise thermal detection connected to the fire alarm system will be installed inside each dwelling unit and cleaning staff closet.
- Smoke detection connected to fire alarm system at top of each exit stair shaft.
- Alarm bell or horn in each dwelling unit and exit stair shaft.
- System operation will be such that activation of any automatic devices in the system will case all alarm signalling devices on the system to sound.

ii. Article 9.9.9.1. Travel Limit to Exit or Egress Doors

It is necessary to travel from the third storey down more than one storey to reach the exterior entrance/exit door of unit A1E. All other units comply with Article 9.9.9.1.

The Applicant submitted that it is not feasible to install an exterior balcony for the third storey of this unit.

The Applicant submitted that sufficiency of compliance is achieved due to the fire alarm and detection system being installed, an exterior balcony at the second floor, and an existing unrated enclosure between the second storey and the stairs leading down to the exterior door.

iii. Article 9.9.2.6. Ancillary Rooms

The Applicant submitted that a maid's closet containing linen and an electrical circuit breaker panel are located in the typical interior exit stair serving four dwelling units.

The existing door is 32 mm thick wood in 20 mm thick wood door frames. The doors have self-latching devices but not self-closing devices.

Some of the maid's closets contain a janitor sink. The janitor sink will be removed which means the Building Code requirement for ventilation will not be applicable.

Fire stopping deficiencies between the closet and the remainder of the building will be upgraded to comply with the Building Code.

The existing doors will be replaced with a labelled 3/4 hour frame complete with self-closing and self-latching devices.

A thermal detector connected to the new fire alarm system will be installed in each closet.

iv. Article 9.9.4.5. Openings in Exterior Walls of Exits

The Applicant submitted that an unrated window in the exterior wall of the typical exit stair serving 4 units is at right angles and within 3 m of unprotected unit windows.

The Applicant proposed to protect the exit windows with wired glass in accordance with the requirements above except that hardwood frames and glazing stops will be used instead of steel.

The Applicant submitted that the proposed frames and glazing stops of hardwood rather than steel are considered reasonable given the existing combustible construction in which they will be installed, the limited building height of three storeys, the limited number of dwelling units (four), and the proposed fire alarm and detection system that will provide early warning of an emergency.

2. **Chief Building Official's Position**

The Respondent submitted that the buildings must be upgraded for compliance with the Building Code that applied at the time of original permit application and construction rather than the retrofit legislation in the Fire Code.

The Respondent also submitted that the existing buildings will not be brought into compliance with the egress requirements of the Building Code as the result of the proposed renovations and the Respondent does not have the authority to issue a building permit based on the proposed equivalencies.

It is the Respondent's opinion that each of the suites or dwelling units contained in the structure normally referred to as Chateau Ridge requires a second exit. Furthermore, the Respondent is not prepared to issue a permit for equivalency measures without first having received confirmation from the Building Code Commission that an alternate proposal to provide adequate fire safety does not compromise the safety of the building.

3. **Commission Ruling:**

It is the decision of the Building Code Commission that sufficiency of compliance with the requirements of Articles 9.9.9.3., 9.9.2.6., 9.9.4.5. and Sentence 9.9.9.1.(3) of the Building Code is obtained provided:

1. a ULC listed fire alarm and detection system, installed in accordance with CAN/ULC - S524-M "Standard for the Installation of Fire Alarm Systems" is provided in all dwelling unit blocks with pull stations at each exit from a stairwell to the exterior. Fire alarm systems shall be monitored through a central monitoring station as required under Sentence 3.2.4.7.(3) of the Building Code.
2. smoke detectors are installed in all electrical and maids closets within the stairwell enclosures and at the top of each stairwell enclosure and rate of rise heat detectors within each dwelling unit are installed.
3. a second means of egress or an accessible exterior balcony is provided for all two storey dwelling units where more than one storey must be traversed to reach an exit.
4. openings in exterior walls of exits are protected with wired glass, mounted in hardwood frames with glazing stops.
5. 45 minute rated fire doors with self closing devices must be installed for each maids closet that opens within the stairwell enclosures.

4. **Reasons:**
    0. The buildings provide for limited occupant loads and limited travel distance.
    1. An early warning and evacuation system will be provided to enhance life safety.
    2. Balconies provide an open space for emergency egress.

RULING

1. **The Applicant**

   Mr. Joseph O'Reiley, Ford Motor Company of Canada is the holder of a permit under the Building Code Act, 1992 to construct a Truck Body Shop at the Ford Motor Company of Canada, 1 Canadian Road, Oakville, Ontario.

2. **Description of Constrution**

   The proposed body shop building is fully sprinklered Low Hazard Industrial (i.e. Group F, Division 3) occupancy. The building is one storey in height and is provided with a standpipe and hose system, and fire alarm system.

   An underground water main circles the building and supplies the individual sprinkler zones. Each sprinkler system is individually controlled by an underground gate valve with a post indicator (PIV) located outside the building about 12 m (40 ft) away from the building wall. All 31 of the outside PIV's are locked fully open.

3. **Dispute**

The dispute between the Applicant and Respondent concerns sufficiency of compliance with the technical requirements of Sentence 3.2.4.16.(5) and Article 3.2.2.12. of the Building Code. At issue is whether locked open outside post indicator valves controlling the water supply for a sprinkler system must be electrically supervised in order to obtain a roof rating waiver under Article 3.2.2.12. of the Building Code.

4. **Provision of the Building Code**

Article 3.2.2.12. Sprinklers in lieu of Roof Rating

1. The requirements in Articles 3.2.2.16. to 3.2.2.62. for the roof assemblies to have a fire-resistance rating are permitted to be waived provided
    a. the building is sprinklered,
    b. the sprinkler system in Clause (a) is electrically supervised in conformance with Sentence 3.2.4.16.(5), and
    c. the operation of the sprinkler system in Clause (a) will cause a signal to be transmitted to the fire department in conformance with Sentence 3.2.4.7.(3).

Sentence 3.2.4.16.(5) Sprinklers in Lieu of Heat Detectors

5. The sprinkler system referred to in Sentence (1) shall be electrically supervised to indicate a trouble signal on the building fire alarm system annunciator for each of the following:
    a. movement of a control valve handle,
    b. loss of excess water pressure required to prevent false alarms in a wet pipe system,
    c. loss of air pressure in a dry pipe system,
    d. loss of air pressure in a pressure tank,
    e. a significant change in water level in any water storage container used for fire fighting purposes,
    f. loss of electrical power to any automatically starting electrical fire pump, and
    g. a temperature approaching the freezing point in any dry pipe valve used for fire fighting purposes.

5. **Applicant's Position**

The Applicant submitted that the outside PIV's are locked fully open with breakable locks, and are inspected weekly. Inspection records are kept.

The Applicant submitted that sufficiency of compliance with Clause 3.2.4.16.(5)(a) of the Building Code has been achieved for the following reasons:

a. Installation of sprinkler systems for compliance with the Building Code is governed by NFPA 13. The building is required to be sprinklered, and complies with NFPA 13 which offers four options to ensure that valves are open and locking is one of them.
b. NFPA does not mandate electrical supervision of valves in existing, large spread plants, due to the cost of such a system.
c. Ford Motor Company of Canada operates its own fire response crew 24 hours per day, 365 days per year, and it is this team that would be the first to respond to any fire emergency. Any information regarding closed valves would be relayed to the Oakville Fire Department upon their arrival.
d. The intent of the Building Code and the NFPA 13 is to ensure valves are open to sprinkler systems, so that early control of any fire is achieved. With all valves open, each sprinkler system is ready to operate at all times.
e. Watchmen make regular rounds and also inspect valves to ensure that they are open.

The Applicant also submitted that locking PIV's open meets the intent of the Building Code, and provides the necessary level of safety to the occupants. Therefore, the roof rating waiver allowable when supervised sprinkler systems are installed should be permitted.

2. **Chief Building Official's Position**

The Respondent submitted that all valves controlling water supplies to the sprinkler system must be electrically supervised in accordance with Sentence 3.2.4.16.(5) in order for the roof rating to be waived under Article 3.2.2.12. of the Building Code.

3. **Commission Ruling:**

It is the decision of the Building Code Commission that providing locked open outside post indicator valves in lieu of electrical supervision of the water control valves to the sprinkler system does not provide sufficiency of compliance with Clause 3.2.2.12.(1)(b) of the Building Code to waive the fire resistance rating of the roof assembly.

4. **Reasons:**
    1. The Building Code requires the specific condition of electrical supervision to waive the roof assembly.

2. Limited security and inspection procedures were not persuasive in accessing the increased reliability of the system through alternative supervision

Dated at Toronto, this 21st day, in the month of November, in the year 1995, for application number 1995-59.

BCC Ruling No. 95-56-476

RULING

1. **The Applicant**

   Mr. Les Cam, Parks and Recreation Department, City of Mississauga is an applicant for a permit under the Building Code Act, 1992 to construct a two storey complex of 12,000 m? containing one Olympic size rink, three professional size rinks, a licensed restaurant, snack bar, skills arcade, shop and toddler play area.

2. **Description of Constrution**

   The Four Rinks Arena is protected by automatic sprinklers throughout and is classified as a Group A, Division 3 occupancy. This two storey complex has a building area of 12,000 m?. It containing four rinks, a licensed restaurant, snack bar, skills arcade, shop and toddler play area. The four rinks occupy the ground floor level and are arranged in quadrants with a lobby bisecting the complex for public access. Directly above the ground floor level is the second level lobby. In accordance with Article 3.2.2.27. of the Building Code fire separations would be required, as follows:

   - horizontal floor assembly, 2h fire resistance rating, second level lobby

- vertical wall assembly utilizing glazing and automatic sprinklers, meeting the horizontal separation, 2h fire resistance rating, second level lobby/overview of rinks since visual openings are desired to each rink.

The Applicant is proposing an interconnected floor space for this Group A, Division 3 occupancy contrary to Clause 3.2.8.2.(6)(c) of the Building Code.

3. **Dispute**

The dispute between the Applicant and Respondent concerns sufficiency of compliance with the technical requirements of Clause 3.2.8.2.(6)(c) of the Building Code. At issue is whether an interconnected floor space is permitted in this Group A, Division 3 occupancy without conforming to the requirements of Articles 3.2.8.3. to Article 3.2.8.11. of the Building Code.

4. **Provision of the Building Code**

Sentence 3.2.8.2.(6) Exceptions to Special Protection

6. An interconnected floor space need not conform to the requirements of Articles 3.2.8.3. to 3.2.8.11. provided
   a. the interconnected floor space consists of the first storey, and the storey next above it, but not both,
   b. the interconnected floor space is sprinklered, and
   c. the interconnected floor space contains only Group A, Division 1 or 2, Group D, Group E, or Group F, Division 3 major occupancies.

2. **Applicant's Position**

The Applicant submitted that consideration should be given by the BCC to permit an interconnected floor space in this arena complex without the necessity of full compliance with interconnected floor space requirements of Articles 3.2.8.3. to 3.2.8.11. of the Building Code.

The Applicant submitted that an interconnected floor space is permitted for Group A, Division 1 & 2 occupancies in accordance with Sentence 3.2.8.2.(6) of the Building Code.

The Applicant submitted an analysis of occupant load, mobility of persons, fuel load and construction requirements to demonstrate that no greater hazard exists to occupants in this Group A, Division 3 arena by way of an interconnected floor space than would exist in a Group A, Division 1 or 2 occupancy where an interconnected floor space is permitted.

The Applicant also submitted that a revision included in the 1995 National Building Code permits Group A, Division 3 major occupancies to be contained in a building in which the first storey and the storey above it are interconnected.

3. **Chief Building Official's Position**

The Respondent submitted that an interconnected floor space is being proposed between level 1 and 2 in a Group A, Division 3 occupancy. The Building Code clearly does not permit an interconnected floor space in a Group A, Division 3 major occupancy without conforming to the requirements of Article 3.2.8.3. to 3.2.8.11.

The Respondent also submitted that the Applicant did not propose any additional measures to demonstrate sufficiency of compliance with the Building Code.

4. **Commission Ruling:**

It is the decision of the Building Code Commission that the interconnected floor space in an Assembly, Division 3 (i.e. A-3) major occupancy provides sufficiency of compliance with Sentence 3.2.8.2.(6) of the Building Code subject to a fire separation being provided between the viewing galleries and the rinks consisting of wired glass in fixed steel frames of unlimited area or a window sprinkler assembly authorized by the Building Materials Evaluation Commission (BMEC).

5. **Reasons:**
    6. Fire separations without fire resistance ratings are provided at the first floor level to act as a smoke barrier.
    7. The fire separation at the 2nd floor level provides increased time to evacuate the 2nd floor level under fire conditions.
    8. Changes to the National Building Code 1995 edition will be extended to address interconnected floor spaces in A-3 major occupancies.

Dated at Toronto, this 21th day, in the month of November, in the year 1995, for application number 1995-64.

RULING

1. **The Applicant**

   Mr. A. Braekevelt, Lambton County Roman Catholic Separate School Board is the holder of a permit under the Building Code Act, 1992 to construct three new school buildings, as follows:

   - St. Francois Xavier Secondary School, 901 Rapids Parkway, Sarnia;
   - St. Anne Elementary School, 1000 Rapids Parkway, Sarnia; and,
   - St. Christopher Secondary school, 1001 Rapids Parkway, Sarnia.

2. **Description of Constrution**

The following applies to the school buildings being constructed by the Lambton County Roman Catholic Separate School Board:

St. Francois Xavier Secondary School	two storey	32,659 m²
St. Anne Elementary School	one storey	32,376 m²
St. Christopher Secondary School	two storey	58,680 m²

The subject schools will be sprinklered and of noncombustible construction. Each building will have a fire alarm and detection system.

The exterior wall construction includes the following, starting from the interior of the building:

- concrete masonry
- sprayed polyurethane insulation (flame spread rating greater than 25)
- air space ranging 25 mm - 40 mm
- face brick

The exterior wall cavity is not firestopped.

3. **Dispute**

The dispute between the Applicant and Respondent concerns sufficiency of compliance with the technical requirements of Sentences 3.1.11.2.(1) and (2) of the Building Code. At issue is whether the construction of the proposed exterior cavity wall requires firestopping.

4. **Provision of the Building Code**

Sentences 3.1.11.2.(1) and (2) Fire Stopping in Wall Assemblies

1. Except as permitted in Sentence (2), fire stops conforming to Article 3.1.11.7. shall be provided to block off concealed spaces within a wall assembly
    a. at every floor level,

b. at every ceiling level where the ceiling forms part of an assembly required to have a fire-resistance rating, and
c. so that the maximum horizontal dimension is not more than 20 m (65 ft 7 in) and the maximum vertical dimension is not more 3 m (9 ft 10 in).

2. Fire stops conforming to Sentence (1) are not required provided
   a. the wall space is filled with insulation,
   b. the exposed construction materials and any insulation within the wall space are noncombustible, or
   c. the exposed construction materials and any insulation within the wall space have a flame-spread rating of not more than 25 on any exposed surface or on any surface that would be exposed by cutting through the material in any direction and fire stops are installed so that the vertical distance between them does not exceed 10 m (32 ft 10 in).

5. **Applicant's Position**

The Applicant submitted that sprayed polyurethane insulation with a flame-spread rating of more than 25 is proposed for the wall cavity between the concrete masonry and exterior face brick. No firestopping of the exterior wall cavity is intended. The Applicant submitted that the proposed exterior wall assembly can be considered to provide sufficiency of compliance with the provision to firestop the concealed space between the insulation and the face brick on the basis that:

0. The concrete masonry wall can be considered the exterior wall assembly with the insulation, air space and exterior face brick considered cladding only.
1. The fire cannot spread from floor to floor through the wall cavity since there is a continuous, unpenetrated concrete block wall.
2. Firestopping of the cavity would defeat the purpose of the rain screen principle which is not the intent of the Building Code.
3. Building Code Commission Decision #88-6-217 for the cavity wall designed in accordance with the rain screen principle was that firestopping of the wall cavity is not required or intended by the Building Code.

6. **Chief Building Official's Position**

The Respondent submitted that Subsection 3.11.2. of the Building Code clearly requires that concealed spaces within a wall assembly that contains a material with a flame spread rating greater that 25 be firestopped.

The Respondent further submitted that based on the nature of the occupancy, the toxicity of the proposed insulation in a fire condition and its flame spread rating characteristics, it would be inappropriate to waive the firestopping requirements.

7. **Commission Ruling:**

It is the decision of the Building Code Commission that the proposed exterior cavity wall construction details do not provide sufficiency of compliance with Sentences 3.1.11.2.(1)&(2) of the Building Code for fire stopping in cavity wall assemblies.

8. **Reasons:**
   - Products are available with flame spread ratings of 25 that will satisfy the provisions of the Building Code which do not impact on the rain screen principle.
   - i. The cavity air space in the wall detail exceeds 25 mm in dimension.
   - ii. No test data was presented concerning fire spread for combustible insulation in wall cavities having an air space exceeding 25 mm in dimension.

Dated at Toronto, this 14th day, in the month of November, in the year 1995, for application number 1995-61.

RULING

1. **The Applicant**

   Mr. Peter Brown, Pratt & Whitney Canada Inc., is the holder of a permit under the Building Code Act, 1992 to construct an addition to an existing second floor office space at Pratt & Whitney, Mississauga Plant, 1801 Courtney Park Drive, Ontario.

2. **Description of Constrution**

   The subject building functions as a manufacturing, assembly and testing repair facility for aircraft engines and components. It is classified as a Group F, Division 2 major occupancy. The building is a two storey, fully sprinklered structure, facing 3 streets.

   At the east end of the manufacturing plant exists an office space that has undergone an expansion. Additional area has been added to the second floor of the office space.

   The ceiling return-air plenum system in the new expansion space has been equipped with FT4 cable.

   The office expansion area has 3 HVAC units which re-circulate air within its own confined space. Air is not re-circulated beyond the smoke compartment.

3. **Dispute**

The dispute between the Applicant and Respondent concerns sufficiency of compliance with the technical requirements of Article 3.5.4.3. of the Building Code. At issue is whether FT4 cables and smoke detectors that would shut down the HVAC units may be installed within the air-return plenum space in the office extension in lieu of FT6 cables.

4. **Provision of the Building Code**

Article 3.5.4.3. Plenum Requirements

1. The concealed space between the ceiling and floor or ceiling and roof used as a plenum need not conform to Sentence 3.1.5.14.(1) and Article 6.2.3.2. provided
    a. all materials within the ceiling space have a flame- spread rating of not more than 25 and a smoke developed classification of not more than 50, except for
        i. tubing for pneumatic controls,
        ii. ptical fibre cables and electrical wires and cables that exhibit a flame-spread of not more than 1.5m (4 ft 11 in), a smoke density of not more than 0.5 at peak optical density and a smoke density not more than 0.15 at average optical density when tested in conformance with the Flame and Smoke Test in the Appendix to CSA C22.2 No. 0.3, "Test Methods for Electrical Wires and Cables" (FT6 Rating),
        iii. optical fibre cables and electrical wires and cables that are located in totally enclosed noncombustible race-ways, and
        iv. single conductor electrical wires and cables that exhibit a vertical char of not more than 1.5 m (4 ft 11 in) when tested in conformance with the Vertical Flame Test - Cables in Cabletrough in Clause 4.11.4. of CSA C22.2 No. 0.3, "Test Methods for Electrical Wires and Cables" (FT4 Rating), and
    b. the supports for the ceiling membrane are of noncombustible material having a melting point not below 7600C (14000F).
2. When the concealed space referred to in Sentence (1) is used as a return-air plenum and incorporates a ceiling membrane that forms part of the required fire-resistance rating of the assembly, every opening through the membrane shall be protected by a fire stop flap which shall
    a. stop the flow of air into the concealed space in the event of a fire,

b. be supported in a manner that will maintain the integrity of the ceiling membrane for the duration of time required to provide the required fire-resistance rating, and
c. conform to CAN4-S112.2-M, "Standard Method of Fire Test of Ceiling Firestop Flap Assemblies".

3. Asbestos paper shall not be exposed in supply and return-air systems.

5. **Applicant's Position**

The Applicant submitted that sufficiency of compliance would be achieved as follows:

- smoke detectors would be installed within the plenum space for each of the three HVAC units; and,
- the HVAC units will be interconnected, therefore, the shut down of one will cause all systems to shut down. Once a smoke detector is activated, the air system no longer functions as a return-air plenum.

The Applicant also submitted that the Building Code would permit an FT4 classification of cable in a ceiling space which is not used as a return-air plenum

6. **Chief Building Official's Position**

The Respondent submitted that a second storey office addition has been constructed over an existing shop area which has also been renovated to create office space. FT4 cables have been installed in the ceiling spaces of both storeys which are used as return air plenums.

The Respondent submitted that Article 3.5.4.3. of the Building Code allows only single conductor wires and cable to have an FT4 rating. All other exposed cables require an FT6 rating.

The Respondent submitted that there is approximately 100,000 lineal feet of FT4 cable installed at this project contrary to Article 3.5.4.3. The Building Code does not provide for the installation of smoke detectors as an alternate to FT6 rated cable.

7. **Commission Ruling:**

It is the decision of the Building Code Commission that the installation of FT4 cable in the plenum space provides sufficiency of compliance with Article 3.5.4.3. of the Building Code provided duct type smoke detectors connected to the fire alarm system are installed within the return air space which will shut down all the H.V.A.C. units within the second floor addition on activation.

8. **Reasons:**
    . The air handling system serves only the second floor addition.
    i. The building is sprinklered.
    ii. Evidence indicates only 25% of the communications cable are not enclosed in a conduit or metallic raceway.

Dated at Toronto, this 14th day, in the month of November, in the year 1995, for application number 1995-63.

RULING

1. **The Applicant**

   Mr. Jack McGee, President, Jack McGee Holdings Ltd. is the applicant for a permit under the Building Code Act, 1992 to construct a vehicle showroom addition to the existing automobile dealership building, at Jack McGee Chevrolet-Oldsmobile-Cadillac Ltd., 1053 Clonsilla Avenue, Peterborough, Ontario.

2. **Description of Constrution**

   The existing building is a two storey building of combustible construction with a building area of 2235 m² (24,059 ft²). A single storey addition of 304 m² (3,270 ft²) is proposed at the south-west corner, resulting in a combined building area of 2,539 m² (27,329 ft²). The proposed new addition is of combustible construction, and fire access routes are provided to all four sides of the building. Most of the main floor is used for functions related to car servicing and body work. The showroom occupies only about 17% of the main floor. The second floor is used for parts storage and offices.

3. **Dispute**

The dispute between the Applicant and Respondent concerns sufficiency of compliance with the technical requirements of Clause 3.2.2.52.(1)(b) of the Building Code. At issue is whether increasing the allowable unsprinklered building area of 2,400 m² (25,800 ft²) by 142 m² (1,529 ft²) i.e. 6 percent and providing fire access routes to all four sides of the existing building and proposed addition will negate the need to provide an automatic sprinkler system.

4. **Provision of the Building Code**

Clause 3.2.2.52.(1)(b) Industrial Buildings, Division 2, up to 4 Storeys

1. A building classified as Group F, Division 2 shall conform to Sentence (2) provided the building
    a. is not more than 4 storeys in building height,
    b. if unsprinklered, has a building area not more than the value in Table 3.2.2.T., and
    c. if sprinklered, is not more than twice the area limits of Clause (b).

5. **Applicant's Position**

The Applicant submitted that the proposed vehicle showroom addition of 3,151 ft² when added to the existing dealership building of 2235 m² (24,059 ft²), slightly exceeds the 2,400 m² (25,800 ft²) of maximum allowable building area for an unsprinklered building facing 3 streets.

The Applicant submitted that the new combustible construction conforms to the existing building construction. The proposed new showroom area when added to the existing building area exceeds the maximum allowable building area by 142 m² (1,529 ft²) for a two storey unsprinklered building facing three streets. Except for a 1.5 m (5 ft) grass perimeter strip, asphalt paving covers the entire site permitting fire access routes on all four sides of the building.

The Building Code does not give credit for buildings facing "four streets", an advantage the Applicant submitted should be considered for the proposed 27,329 ft² building.

6. **Chief Building Official's Position**

The Respondent submitted that the proposed addition results in a building area greater than permitted by the Article 3.2.2.52. of the Building Code for a building of combustible construction.

The Respondent submitted that the Building Code provides solutions such as reducing building area by constructing a firewall, or doubling allowable building area by sprinkling the building.

The applicant wishes to increase allowable building area by providing fire access routes so the building can be considered to face 4 streets. The Building Code does not give credit for facing more than 3 streets.

The Respondent also submitted that only one face on the building perimeter is within 90 m of a hydrant. Therefore, the building does not meet the requirement to be considered to face 3 streets. It is the position of the Respondent that the building only faces one street.

The Respondent stated that the municipality supports the Applicant's position provided an additional hydrant is installed making the building face 3 streets.

7. **Commission Ruling:**

   It is the decision of the Building Code Commission that the proposed addition provides sufficiency of compliance with Article 3.2.2.52. of the Building Code for buildings facing three streets, provided an additional fire hydrant is installed in accordance with Article 3.2.5.8. of the Building Code.

8. **Reasons:**
   1. The proposed addition is small accounting for less than 15% of the total building area.
   2. The building has been provided with a number of fire separations between areas within the building.
   3. Approximately 40% of the existing building is of non-combustible construction.
   4. Fire access routes have been provided around the entire perimeter of the building.

Dated at Toronto, this 10th day, in the month of November, in the year 1995, for application number 1995-54.

RULING

1. **The Applicant**

   Ms. Mary Welsh, Owner, Darling Court Developments Inc., is the holder of a permit under the Building Code Act, 1992 to construct a two storey courthouse building at 44 Queen Street, Brantford, Ontario.

2. **Description of Constrution**

   The subject building is a newly constructed two storey courthouse with a partial basement. It is of noncombustible construction and has a building area of 1,468 m? (15,801 ft?) and is provided with a fire alarm system. Prisoners' areas are located on the main floor of the building. An elevator is provided within these areas to transport prisoners to and from the courtrooms on the second floor. Automatic sprinklers and smoke detectors are installed in the detention areas.

3. **Dispute**

The dispute between the Applicant and Respondent concerns sufficiency of compliance with the technical requirements of Articles 3.3.3.9. and 3.2.4.12. of the Building Code. At issue is whether not providing smoke detectors and sprinkler heads in the prisoner cell areas and prisoner holding areas, and not sprinklering the prisoner elevator shafts provide sufficiency of compliance with the Building Code, at Ontario Court Justice (Provincial Division), 44 Queen Street, Brantford, Ontario.

4. **Provision of the Building Code**

Articles 3.2.4.12. Smoke Detectors

1. Where a fire alarm system is required, smoke detectors shall be installed in
    a. every sleeping room and corridor in portions of buildings classified as Group B major occupancy,
    b. every room in a contained use area and corridors serving those rooms
    c. every corridor in portions of buildings classified as Group A, Division 1 major occupancy,
    d. every public corridor in portions of buildings classified as Group C major occupancy,
    e. every exit stair shaft, and
    f. every corridor serving classrooms in elementary and secondary schools.

Articles 3.3.3.9. Contained Use Areas

2. A contained use area shall conform to Sentences (2) to (5).
3. A contained use area shall be separated from the remainder of the building by a fire separation having a fire-resistance rating of not less than 1 h.
4. Except as permitting in Sentence (5), a contained use area shall be sprinklered.
5. The actuation of the sprinkler system required by Sentence (3) shall initiate an alert signal or an alarm signal on the fire alarm system.
6. A contained use area is not required to be sprinklered as required by Sentence (3) if
    a. the building is designed so that during a period of 2 h after the start of a fire in the contained use area, other fire compartments will not contain more than 1 per cent by volume of contaminated air from the contained use area.
    b. the building is designed so that during a period of 2 h after the start of a fire in another part of the building, the contained use area will not contain more than 1 per cent by volume of contaminated air from the other part of the building,

c. all doors are designed to be remotely released in conformance with Sentence 3.3.1.12.(2), and
d. the contained use area does not contain any rooms lined with combustible padding.

5. **Applicant's Position**

The Applicant submitted the following comments to support the removal of the sprinkler heads and heat/smoke detectors:

1. The detention cells at 44 Queen Street are not used for the overnight lodging of prisoners. All prisoners in custody will be under active visual observation, either personally or video, monitoring by Court Security Special Constables employed and trained by the Brantford Police Service.
2. The placement of sprinkler heads and heat/smoke detectors in detention cells within the physical reach of prisoners pose a very real physical threat to prisoners and security staff.

   Tamper-proof sprinkler heads and heat/smoke detectors are not a reality. The Brantford Police Service has actual experience in this matter. During the construction of the police headquarters, so called "tamper-proof" units were installed contrary to their wishes in the detention cells. Within two months, they were removed. Prisoners had removed wafer-like pieces from the sprinkler and used them in attempts to slash their wrists.

3. The placement of sprinkler heads and heat/smoke detectors in the detention cells at 44 Queen Street will lead to unnecessary inconvenience and down time in the Courts. Our security personnel will take every precaution to ensure that prisoners in custody are not in possession of cigarettes, matches, etc.; however, there will not doubt be times when due to the number of prisoners in custody, even the most rigid precautions will be circumvented.

   Should that lead to the setting off of the fire alarms and sprinkler systems, the entire building will be subject to evacuation, thus disrupting court proceedings. All prisoners will be returned to their detention areas until the source and nature of the alarm is determined.

   The Brantford Fire Department will be inconvenienced by having to respond to the alarm. The downtown area will be disrupted while emergency vehicles respond to the alarm. During this time, Court proceedings will be recessed until the prisoners are secured and

the clean up of any water is completed. This will undoubtedly, result in the adjournment of matters scheduled for hearings and the backlogging of future court dates.

6. **Chief Building Official's Position**

   The Respondent submitted that smoke detectors and sprinklers are required in contained use areas in accordance with Articles 3.3.3.9. and 3.2.4.12 of the Building Code.

7. **Commission Ruling:**

   It is the decision of the Building Code Commission that not providing smoke detectors and sprinkler heads in the prisoner cells, prisoners holding areas and prisoner elevator shaft does not provide sufficiency of compliance with the provisions of the Building Code.

8. **Reasons:**
   1. The Building Code, Article 3.3.3.9. provides alternatives for deleting sprinklers in contained use areas.
   2. The Applicant provided no design alternatives to be considered by the Commission that could provide sufficiency of compliance.
   3. Design alternatives to the currently installed fire alarm system exist to minimize the impact of false alarms.

Dated at Toronto, this 10th day, in the month of November, in the year 1995, for application number 1995-60.

BCC Ruling No. 95-51-471

RULING

1. **The Applicant**

   Mr. Mario Fatica, IPCF Properties Inc. is an applicant for a permit under the Building Code Act, 1992 to construct a one storey retail food store (i.e. Loblaws) with a basement parking garage at 173 Lakeshore Road West, Oakville, Ontario.

2. **Description of Constrution**

   The subject building is to be used as a retail food store (i.e. Loblaws). The building is one storey in building height and has a building area of 5,378.0 m² (57,896.6 ft²).

   The basement of the building will be used as an underground parking garage. The ground floor of the building will be used as the food store. The food store will contain three separate mezzanines.

   The following factors apply to the subject building:

   - retail store is fully sprinklered
   - underground basement is not sprinklered
   - building faces two streets for fire department access (i.e. 50% of building perimeter)
   - basement underground parking garage is a Group F, Division 3 occupancy

- ground floor retail store is a Group E occupancy
- noncombustible construction (i.e. subsection 3.1.5.) will be used for this facility
- fire alarm system with an annunciator will be provided

3. **Dispute**

The dispute between the Applicant and Respondent concerns an interpretation of the technical requirements of Sentence 3.2.9.1.(1) of the Building Code. At issue is whether the sprinklered retail store and unsprinklered open air basement parking area provides sufficiency of compliance with the requirements for a fully sprinklered building, thereby eliminating the requirement to provide a standpipe and hose system in the basement parking garage.

4. **Provision of the Building Code**

Article 3.2.9.1. Requirement for Standpipe and Hose Systems

Except as provided in Article 3.2.9.2., a standpipe and hose system shall be installed in every building that:

a. is more than
   i. 3 storeys in building height, or
   ii. 14 m in height measured between grade and the ceiling of the uppermost storey,
b. is greater in building area than the area shown in Table 3.2.9.A. for the applicable building height shown in the Table where the building
   i. is not sprinklered, and
   ii. is not more than 14 m high measured between grade and the ceiling of the top storey, or
c. contains more than one storey below grade.

5. **Applicant's Position**

The Applicant submitted that the parking garage is classified as a basement, but also meets the requirements for an open air storey under the Building Code. The first storey retail potion of the building is required to be provided with an automatic sprinkler system to meet the construction requirements in Article 3.2.2.44. of the Building Code.

The Applicant submitted that Sentence 3.2.1.5.(2) of the Building Code permits open air storeys to be unsprinklered regardless of whether it is a basement, an above grade storey or within a sprinklered building.

The Applicant submitted that due to the first storey being sprinklered, Subclause 3.2.9.1. (1)(b)(i) waives the requirement for a standpipe and hose system for the storey. Furthermore, the Applicant submitted that Clause 3.2.9.1.(1)(c) waives the requirement for a standpipe and hose system in the basement level.

6. **Chief Building Official's Position**

The Respondent submitted that the basement parking garage is required to be provided with a standpipe and hose system.

The Respondent submitted that the building referenced in Article 3.2.9.1. consists of both the first storey and basement level. Therefore, since the entire building is not sprinklered a standpipe and hose system is required.

7. **Commission Ruling:**

It is the decision of the Building Code Commission that providing a standpipe and hose system only in the basement open air parking garage provides sufficiency of compliance with Article 3.2.9.1. of the Building Code.

8. **Reasons:**
   . The entire building cannot be considered fully sprinklered and therefore the exception of Clause 3.2.9.1.(1)(b) does not apply.
   i. The first floor retail use is sprinklered.

Dated at Toronto, this 26th day, in the month of October, in the year 1995, for application number 1995-45.

RULING

1. **The Applicant**

   Mr. Harry Cavender, Fanshawe College, London is the applicant for a permit under the Building Code Act, 1992 to construct a new College building as an addition to an existing high school that would permit the shared utilization of various rooms and facilities at Bill Martyn Parkway, St. Thomas, Ontario.

2. **Description of Constrution**

   The subject building is a new campus facility for Fanshawe College. The new one storey facility is proposed to be connected to the existing St. Joseph's High School. The proposed connection will traverse a property line. The properties on both sides of the property line will be separately owned by the college and the high school.

   The proposed connection of the college and high school facilities is intended to cost effectively facilitate sharing of a library- resource centre and cafeteria spaces.

   The following matters apply to the existing building and the proposed addition:

   i. Existing St. Joseph's High School
      - building height of one storey

- sprinklered
- noncombustible construction
- building area: 7520 m²
- building faces one street for fire department access
- roof assembly is not rated per sprinkler waiver in Article 3.2.2.12.
- equipped with a single stage fire alarm and detection system
- sprinklers provide primary means of fire detection and suppression
- construction completed in 1993
- major occupancy: Group A, Division 2 assembly occupancy
- construction classification: Article 3.2.2.22.

ii. New Fanshawe College Expansion:

- building height of one storey
- fully sprinklered
- noncombustible construction
- building area of expansion: 3868 m²
- building faces one street for fire department access
- roof assembly is not rated per sprinkler waiver in Article 3.2.2.12.
- fire alarm system in high school expanded to serve college (i.e. single system throughout)
- sprinklers provide primary means of fire detection and suppression
- major occupancy: Group A, Division 2 assembly occupancy
- construction classification: Article 3.2.2.22.

3. **Dispute**

The dispute between the Applicant and Respondent concerns sufficiency of compliance with the technical requirements of Article 3.2.3.4. of the Building Code. At issue is whether providing a fully sprinklered building with a 1 hour fire separation between the high school and college in lieu of a party wall (i.e. fire wall) provides sufficiency of compliance with the Building Code.

4. **Provision of the Building Code**

Article 3.2.3.4. Party Wall

Every wall that is a party wall shall be constructed as a firewall.

5. **Applicant's Position**

The Applicant submitted that the college and high school can be treated as a single building. The applicant proposes to address life safety and property concerns in reviewing the high school and college as separate suites under the Building Code. A 1 hour fire separation is proposed between the college and high school spaces.

The Applicant submitted that the Building Code does not prohibit a single building from traversing a property line. Also, the Building Code does not require a building to be separated by a firewall into two buildings solely for the reason of traversing a property line.

The Applicant submitted that Subsection 3.2.3 "Spatial Separation and Exposure Protection of Buildings" addresses exposure requirements for separate buildings and separate fire compartments where such separate buildings or separate fire compartments present an external fire exposure to a separate building or separate fire compartment. The exposure requirements apply to separate buildings and separate fire compartments that may be located on the same property or may be located on separate properties. The exposure requirements apply to external fire exposure. This Subsection does not require an internal fire separation or an internal fire separation constructed as a firewall, to be constructed at a property line where a single building traverses a property line.

The Applicant submitted that Article 3.2.3.4 Party Wall, states, "Every wall that is a party wall shall be constructed as a firewall". Party wall is defined as, "...a wall jointly owned and used by 2 parties under easement agreement or by right in law, and erected at or upon a line separating 2 parcels of land each of which is, or is capable of being, a separate real-estate entity." The requirement and the definition, do not require a party wall/firewall to be constructed at a property line where a single building traverses a property line.

The Applicant submitted that Subsection 3.1.10 "Firewalls", specifies that a firewall must meet depending on the major occupancy of the buildings. This Subsection does not require that a firewall be constructed where a single building traverses a property line.

The Applicant submitted that the college and high school are considered separate suites within a single building of shared ownership. The suites will be separated by a 1 hour fire separation in accordance with Article 3.3.1.1. The Building Code does not require that the fire separation proposed between suites follow the property line.

The Applicant summarized his position that the expanded building, including the 3 year old existing high school can be reviewed under the requirements of the Building Code as a single

building. The building will comply with the Building Code in all respects as a single building. A fire separation will be provided between the college and high school in conformance with the requirements of the Building Code to separate suites.

6. **Chief Building Officials Position**

   The Respondent submitted that Subsection 3.2.3 "Spatial Separation and Exposure Protection of Buildings" and Subsection 3.1.10 "Firewalls", requires the structure to be fire separated into two separate buildings by a firewall along the property line. The reason that this is required is that the structure traverses a property line and that the properties on either side of the property line are separately owned by the high school and college.

   The Respondent concurred that in concept a 1 hour fire separation in a fully sprinklered building as proposed by the Applicant, sufficiently complies with the Building Code. However, the Respondent's position is that sufficiency of compliance must be determined by the Building Code Commission.

7. **Commission Ruling:**

   It is the decision of the Building Code Commission that providing a 1 hour fire separation between the fully sprinklered high school and Fanshawe College provides sufficiency of compliance with Article 3.2.3.4. of the Building Code.

8. **Reasons:**
   1. Both buildings are designed as an Assembly Occupancy Division 2 (A-2) and will be operational as one complex.
   2. Both parties will enter into an agreement with respect to the management, maintenance, and the conditions of future sale of either property.

Dated at Toronto, this 26th day, in the month of October, in the year 1995, for application number 1995-55.

For the Respondent

RULING

1. **The Applicant**

   Mr. Marc J. Simpson, Packaging Resins Manufacturing Manager, Celanese Canada Inc. is the holder of a permit under the Building Code Act, 1992 to construct an eight storey Solid State Polymerization Structure, Millhaven, Ontario.

2. **Description of Constrution**

   The subject building is an 8 storey building classified as a Medium Hazard Industrial Occupancy (Group F, Division 2) having a building area of 278.7 m² (3,000 ft²).

   The applicant proposes to install one rated (code complying exit from each floor area) and a second exit by means of a caged ladder for emergency purposes, since the building will not normally be occupied.

The building will be used for a gravity type flow process, with periodic monitoring and maintenance.

3. **Dispute**

The dispute between the Applicant and Respondent concerns sufficiency of compliance with the technical requirements of Sentences 3.4.2.1.(1) & 3.4.7.1.(1) of the Building Code. At issue is whether the one rated exit and a caged ladder will provide sufficiency of compliance with the exiting requirements of the Building Code.

4. **Provision of the Building Code**

Sentence 3.4.2.1.(1) Minimum Number of Exits

1. Except as provided in Sentences (2) to (4), and (6), every floor area as regulated in Article 3.4.1.1. shall be served by not less than 2 exits.

Sentence 3.4.7.1.(1) Scope

2. Except as provided in Sentence (2), fire escapes shall not be erected on buildings.

5. **Applicant's Position**

The Applicant submitted that the Building Code would require 2 rated exits per floor in an occupied structure. One rated exit is provided adjacent to the elevator shaft on northwest corner. Since the structure is an unoccupied process area, the second exit is provided by means of a caged ladder for emergency exit.

The Applicant also submitted that sufficiency of compliance for two exits per floor is achieved in this unoccupied structure by providing a fully rated exit in the northwest corner and an emergency exit in the form of a caged ladder on the south end of the west wall.

6. **Chief Building Officials Position**

The Respondent submitted that each floor area is required to be served by two exits. One exit stair is located beside the elevator on the north side of the building. The other in dispute is an exterior fire escape located on the southwest corner of the building which does not constitute as a proper exit for a new building.

The Respondent also submitted that the reasons for non- acceptance of the Applicant's proposal are as follows:

a. A fire escape on a new buildings is not permitted and therefore can not be considered a required exit.
b. This ladder type fire escape extends up to 8 floors and is exposed to all weather conditions, thus putting any person who is forced to use it in a life threatening situation.
c. This is a multi-million dollar construction project. Constructing a required separate second exit would not be expensive to the overall project when this company's policy is "safety first".

7. **Commission Ruling:**

It is the decision of the Building Code Commission that the provision of a ladder does not comply with the Building Code for exit requirements.

8. **Reason:**

The structure is considered a building; each level is a storey for exit purposes. A ladder is not deemed an acceptable second means of egress.

Dated at Toronto, this 19th day, in the month of October, in the year 1995, for application number 1995-41.

BCC Ruling No. 95-48-468

BUILDING CODE COMMISSION DECISION ON B.C.C. #95-48-468

IN THE MATTER OF Subsection 24(1) of the *Building Code Act, 1992.*

AND IN THE MATTER OF Articles 1.1.3.2., 2.2.1.1. and 9.8.4.1. of the Revised Regulation of Ontario 1990, Regulation 61, as amended by O.Regs. 400/91, 158/93, 160/93, 355/94 and 20/95 (the "Building Code").

AND IN THE MATTER OF an application by Ms. Dawn Daniel for the resolution of a dispute with Mr. John Wright, Chief Building Official, Town of Markham, concerning whether the close proximity of an exit door to the property line (i.e. 0.55 m) affords adequate access to a public thoroughfare and if the relationship between the exterior grade and the interior landing requires steps that may obstruct the landing, in accordance with Article 1.1.3.2. and Articles 2.2.1.1. and 9.8.4.1. of the Building Code, at 16 Lavron Court, Markham, Ontario.

DATE OF RULING

October 19th, 1995

APPEARANCES

Ms. Dawn Daniel, Owner
Markham, Ontario
The Applicant

Mr. John Wright
Chief Building Official
Town of Markham

RULING

1. **The Applicant**

   Ms. Dawn Daniel is an applicant for a permit under the Building Code Act, 1992 to install a side entrance door to serve an accessory apartment located in the basement of the applicant's house.

2. **Description of Constrution**

   The subject doorway in dispute was installed to serve an accessory apartment located in the basement of the applicant's dwelling.

   The side entrance is located on a wall within 0.6 m of the property line. There is a 1.1 metre (43 inch) maintenance easement between the subject doorway and the adjacent house.

   The threshold of the door is less than 150 mm above the exterior grade and about 0.5 m above the interior landing level. The doorway constitutes the required exit from an accessory apartment located in the basement.

3. **Dispute**

   The dispute between the Applicant and Respondent concerns an interpretation of the technical requirements of Article 1.1.3.2. and Articles 2.2.1.1. and 9.8.4.1. of the Building Code. At issue

is whether the disputed door satisfies the definition of exit, and if the relationship between the exterior grade and the interior landing requires steps that may obstruct the landing.

4. **Provision of the Building Code**

Article 1.1.3.2. Definition of Exits

Exit means that part of a means of egress, including doorways, that leads from the floor area it serves, to a separate building, an open public thorough-fare, or an exterior open space protected from the exposure from the building and having access to an open public thoroughfare.

Article 2.2.1.1. Characteristics of Materials, Appliances, Systems and Equipment

All materials, appliances, systems and equipment installed to meet the requirements of this Code shall possess the necessary characteristics to perform their intended functions when installed in a building.

Article 9.8.4.1. Dimensions of Landings

Landings shall be at least as wide and as long as the width of stairs in which they occur, except that the length of landing for exterior stairs serving not more than 1 dwelling unit need not exceed 900 mm (2 ft 1 in), and the length of landing for all other stairs in a straight run need not exceed 1 100 mm (3 ft 7 in).

5. **Applicant's Position**

The Applicant submitted that the Town of Markham will not allow the side entrance door to serve the accessory basement apartment.

The Applicant submitted that there is a registered easement of 1.1 m (43") between the houses with the property line at 0.55 m (21?") from each house.

6. **Chief Building Officials Position**

The Respondent submitted that the doorway in dispute was installed without a building permit to serve an accessory apartment located in the basement of the Applicant's dwelling. The apartment was established without a building permit. The Applicant has been convicted for construction without a building permit and has made an application for a permit authorizing the disputed door.

The Respondent submitted that the application for a permit was denied primarily on the grounds that the disputed doorway is dysfunctional.

The Respondent submitted that if the Commission rejects this reason, the following particulars contravene the Building Code:

i. the disputed doorway does not satisfy the definition of exit; and,
ii. the relationship between the exterior grade and the interior landing requires steps that obstruct the landing in violation of Article 9.8.4.1.

Article 2.2.1.1. Characteristics of Materials, Appliances, Systems and Equipment

The Respondent considered the doorway to be a system or equipment in the context of Article 2.2.1.1.

The Respondent submitted that the intended function of a doorway is to facilitate the movement of people and things between the spaces it connects. Where a door is a component of an exit system it must also perform that function.

The Respondent submitted that to perform its intended function, a door/doorway must:

iii. be wide enough to accommodate the people and things moving through it (i.e. Article 9.6.3.1. of the Building Code requires that the subject door be at least 760 mm wide); and,
iv. lead to and from a space having the same width.

The doorway in dispute is situated in a wall located 580 mm from the property line. An easement facilitating maintenance of the wall does not provide for trespassing over the adjacent property. The willingness of the abutting neighbour to tolerate such trespass can not be assumed. The easement does not prevent the erection of a fence along the boundary.

The limited proximity of the door to the property line and the absence of any permanent right of access beyond the property line renders this door dysfunctional.

Accordingly, the doorway does not possess the necessary characteristics to perform its intended function and is not permitted by Article 2.2.1.1.

Article 1.1.3.1. Definitions of Words and Phrases

The Respondent submitted that the disputed doorway is a required exit from the basement apartment. All options involving shared egress or egress windows are impractical and are not proposed.

If the disputed doorway is considered a required exit, it must (by definition) lead to an open public thoroughfare, or an exterior open space protected from fire exposure from the building and have access to an open public thoroughfare. The Respondent submitted that a strip of land, less than the width of the exit door does not satisfy this definition.

Article 9.8.4.1. Dimensions of Landings

The Respondent submitted that the relationship between the exterior grade and the interior landing requires 2 treads that reduce the landing dimensions to approximately half that required by Article 9.8.4.1. This is a significant safety deficiency.

7. **Commission Ruling:**
    1. It is the decision of the Building Code Commission that the exit system including the exterior access to a public thoroughfare cannot be less than the required exit as noted in Article 2.2.1.1. of the Building Code.
    2. It is also the decision of the Building Code Commission that if the width of the exterior access is not less than the minimum unobstructed dimension specified in compliance alternative C121.1(c) of Article 11.2.3.1. for access to a secondary exit from a dwelling unit which leads through another dwelling unit, the access route provides sufficiency of compliance with the Building Code.

The access to the first floor main exit must be maintained free of obstruction at all times.

The exterior access to the public thoroughfare from the secondary exit must be maintained free of obstruction at all times.

8. **Reason:**

The building is greater than 5 years old and Part 11 compliance alternative may be applied, as per 2.1.1.6 of the Building Code.

Dated at Toronto, this 19th day, in the month of October, in the year 1995, for application number 1995-49.

RULING

1. **The Applicant**

   Mr. Louis Aldrovandi, President, Aldrovandi Equipment Ltd. is the applicant for a permit under the Building Code Act, 1992 for a canopy structure over a parking lot at the rear of an existing industrial building.

2. **Description of Constrution**

   The subject building addition is a canopy structure (i.e. roof but no enclosing walls) covering an area of 1055 m² at rear of an existing industrial building.

   The structure abuts the Canadian Pacific Railway (CPR) main line right of way and is 2.12 m from the property line.

   The Applicant contends that the structure is considered a covered vehicle passageway under Article 3.2.3.19. of the Building Code.

3. **Dispute**

The dispute between the Applicant and Respondent concerns sufficiency of compliance with the technical requirements of Article 3.2.3.1. of the Building Code. At issue is whether a canopy structure over a parking lot at the rear of an existing industrial building can be considered a covered vehicle passageway under Article 3.2.3.19. and not be subjected to the spatial separation requirements in Article 3.2.3.1. of the Building Code, at Aldrovandi Equipment Ltd., 191 Vinyl Court, Vaughan, Ontario.

4. **Provision of the Building Code**

Article 3.2.3.1. Limiting Distance and Area of Unprotected Openings

1. Except as provided in Articles 3.2.3.9. to 3.2.3.11, the area of unprotected openings shall not be more than that set forth in Tables 3.2.3.A. or 3.2.3.B. for the limiting distance applicable to the exposing building face under consideration.
2. The area of the unprotected openings in an exposing building face shall be the aggregate area of unprotected openings expressed as a percentage of the area of the exposing building face in Tables 3.2.3.A. and 3.2.3.B.
3. For the purposes of determining the type of construction and cladding and the fire-resistance rating of an exterior wall, the exposing building face shall be taken as the projection of the exterior wall onto a vertical plane located so that no portion of the exterior wall of the building or of a fire compartment, if the fire compartment complies with the requirements of Sentence 3.2.3.2.(1), is between the vertical plane and the line to which the limiting distance is measured and, for these purposes, the area of unprotected openings shall be determined from Table 3.2.3.A. or Table 3.2.3.B.
4. For the purposes of determining the actual percentage of unprotected openings permitted in an exterior wall, the location of the exposing building face is permitted to be taken at a vertical plane located so that there are no unprotected openings between the vertical plane and the line to which the limiting distance is measured.
5. Where fire fighting facilities cannot reach the building within 10 min of the alarm being received, the limiting distance shall be doubled.

Article 3.2.3.19. Covered Vehicular Passageway

6. A covered vehicular passageway shall
    a. be of noncombustible construction when constructed below grade, and

b. be separated from every building or part of a building adjoining it by a fire separation having a fire-resistance rating of not less than 1.5 h where it is designed as a receiving or shipping area.

5. **Applicant's Position**

The Applicant submitted that the structure is a covered vehicle passageway under Article 3.2.3.19. of the Building Code and therefore is not subject to the spatial separation requirements in Article 3.2.3.1.

The Applicant submitted that the structure abuts a main line CPR railway right of way and is 2.12 m from the property line.

6. **Chief Building Officials Position**

The Respondent submitted that Article 3.2.3.19. (i.e. Covered Vehicular Passageway) of the Building Code does not waive the requirement for an exterior spatial separation and exposure protection for the building.

The Respondent also submitted that a railway right of way is not considered a "street" by definition in Subsection 1.1.3. (i.e. Definitions of Words and Phrases) of the Building Code.

The Respondent submitted that the Committee of Adjustment the minimum rear yard setback of 2.12 m subject to the following conditions:

i. That the variance be site specific to the existing canopy and that the canopy not be enclosed to the satisfaction of the Building Standards Department; and,
ii. That if a Building Permit is not issued, based upon the decision of the Committee of Adjustment within twelve (12) months of the date this decision becomes final and binding, the said decision shall expire and shall be deemed to have been annulled and rescinded by the Committee.

7. **Commission Ruling:**

It is the decision of the Building Code Commission that the proposed canopy structure provides sufficiency of compliance with Article 3.2.3.19 and 3.2.3.1. of the Building Code provided that

. it is separated from the existing building by a fire separation having 1? hour fire resistance rating
a. no enclosing wall on the south face

b. space to be used for vehicular storage only.

8. **Reasons:**

0. The existing building is separated by a wall having a 1? hour fire resistance rating.

1. The area is used only for vehicular storage.

2. There is no proposed exposing building wall and the area is unenclosed on three faces.

RULING

1. **The Applicant**

   Mr. R.D. Funnell, City Engineer is the applicant for a permit under the Building Code Act, 1992 to construct a compost building at 333 Watson Road, Guelph, Ontario.

2. **Description of Constrution**

   The plant is a one storey structure of non combustible construction. The plant floor is poured concrete on grade. The walls are a combination of concrete and lined insulated metal panel cladding. The concrete portion of the wall extends 150 mm above grade. The lined insulated metal cladding panel on structural steel extends above the concrete portion of the wall approximately 6 m above the floor level. The roof is a metal roof on structural steel and slopes upwards from the 6 m to a height of 8 m at its peak.

   The plant is divided into two areas. The Primary Compost area and the Secondary Compost area. Between the two areas is transition point called the Discharge Pit.

   The plant will be protected with a fire alarm system conforming to the Building Code Subsection 3.2.4.

Dry pipe sprinkler systems designed to NFPA 13 "Standard for the Installation of Sprinkler Systems" will protect the Secondary Compost area only. The Primary Compost area will have a wetting design to automatically activate once a day.

A 50 mm water line will be provided along the west wall with 8 hose bibs.

The Primary Compost area is divided into 11 compartments of 3 m in height each extending from column 12 to column line 22. The two exterior compartments and centre compartment contain 48 fan units supplying air to the compost from below. The remaining compartments are compost areas having 600 mm of gravel on top of the concrete floor. The 3 m high walls separating these compartments are 300 mm thick poured concrete.

The Secondary Compost area is protected by dry pipe sprinkler systems. The area is open with no compartments. The compost is divided into an east and west area with a 10 m open space in the middle.

3. **Dispute**

The dispute between the Applicant and Respondent concerns sufficiency of compliance with the technical requirements of Sentence 3.2.3.9.(2), Clause 3.4.2.5.(1)(f) and Article 3.2.2.12. of the Building Code. There are three areas of dispute for this facility. The areas of dispute are:

i. East Exposing Building Face

The east exposing building face has a limiting distance permitting 23% maximum unprotected openings as calculated by the Guelph Building Department. Clause 3.2.3.7.(2)(b) requires the exterior wall to be constructed with a 2 hour fire-resistance rating and to be clad with non combustible cladding. The non combustible cladding proposed for the building does not have a fire-resistance rating. The limiting distance was measured from the building face to the property line.

ii. Travel Distance to an Exit

Most areas in the building exceed the maximum travel distance requirement of 30 m for an unsprinklered building.

iii. Considering the Plant Equivalent to a Fully Sprinklered Facility

The building is classified by Article 3.2.2.54. as a Medium Hazard Industrial Occupancy (Group F, Division 2). The construction requirements of the Sentence for an unsprinklered building are:

- non combustible construction
- roof shall have a one hour fire resistance rating

4. **Provision of the Building Code**

Sentence 3.2.3.9.(2) Unlimited Unprotected Openings

2. The exposing building face of a storey that faces a street and is at the same level as the street is permitted to have unlimited unprotected openings if the limiting distance is not less than 9 m.

Clause 3.4.2.5.(1)(f) Location of Exits

3. Except as provided in Sentence (2), (3) and 3.3.2.4.(6), where more than one exit is required from a floor area, such exits shall be located so that the travel distance to not less than one exit as described in Article 3.4.2.4. shall not be more than

(f) 30 m in any other occupancy.

Article 3.2.2.12. Sprinklers in Lieu of Roof Rating

4. The requirements on Articles 3.2.2.16. to 3.2.2.62. for roof assemblies to have a fire-resistance rating are permitted to be waived provided
   a. the building is sprinklered
   b. the sprinkler system in Clause (a) is electrically supervised in conformance with 3.2.4.16.(5), and
   c. the operation of the sprinkler system in Clause (a) will cause a signal to be transmitted to the fire department in conformance with Sentence 3.2.4.7.(3).

2. **Applicant's Position**

The Applicant submitted that through the process of the wetting system in the Primary Compost area and the dry pipe sprinkler systems protecting the Secondary Compost area, the Compost Plant be considered the equivalent to a fully sprinklered building. The Applicant submitted that sufficiency of compliance is met through the following:

- non combustible construction
- limited ignition sources
- 50% moisture content of the compost making ignition extremely difficult
- roof height being between 3 m to 5 m above the upper portion of the compost
- automatic detection for controlling the temperature of the compost
- manual suppression source through the hose outlets
- daily wetting of the compost (the wetting system can also be manually operated)

The Applicant submitted that collectively these meet the intent of the Building Code to provide a building which meets the life safety standards of our society. The systems provide sufficiency of compliance to be considered equivalent to a fully sprinklered building, thereby waiving the one hour fire resistance rating for the roof and its supporting structure.

The Applicant submitted that a timed exit analysis demonstrates that the occupant in the most remote portion of the building may reach the exterior of the building within 1.3 minutes.

The Applicant also submitted that an access road will be designed to support the weight of a fire fighting vehicle conforming to Article 3.2.5.7. of the Building Code. This access road will be open at all times for access by the fire department vehicles and therefore may be considered a street for the application of Sentence 3.2.3.9.(2) permitting unlimited unprotected openings in the east exposed building face. Therefore, the east exterior building face does not require a fire resistance rating.

The Applicant summarized his position by stating the design of the Compost Plant meets the intent of the Building Code and its level of life safety.

2. **Chief Building Officials Position**

The Respondent submitted that the building has been classified as a Medium Hazard Industrial Occupancy (Group F, Division 2). As an unsprinklered building facing one street, the construction requirements of the building shall conform to Sentence 3.2.2.54. of the Building Code. Therefore, the roof assembly requires a 1 hour fire-resistance rating and all loadbearing walls and columns must have the same rating as required for the supported assembly.

The Respondent submitted that the travel distance to an exit shall not exceed 30 m. Most areas in the building exceed the 30 m travel distance requirement.

The Respondent submitted that the exposing building face of the east elevation may have a maximum of 23% unprotected openings, for an unsprinklered building. The remaining 77% must have a 2 hour fire- resistance rating. No rating is proposed by the Applicant.

The Respondent submitted that a stand pipe and hose system is required if the building is not sprinklered.

3. **Commission Ruling:**

It is the decision of the Building Code Commission that the Primary Compost area wetting system does not provide sufficiency of compliance with the sprinklering requirements of the Building Code. The Commission further rules that upon the provision of a sprinkler system throughout the building in accordance with the Building Code requirements, the following provide sufficiency of compliance with Sentence 3.2.3.9.(2) and Article 3.4.2.5.:

0. The non-rated east exposing building face of non-combustible construction.
1. The travel distance to an exit within the Primary Compost area.

4. **Reasons:**

0. The wetting system does not comply with NFPA 13.
1. Internal subdivision of combustible material within the 8 compartmentized channels separated by 3 m high, 300 mm thick concrete walls contains potential fire spread and provides protection for the east exterior wall.
2. The compost material is wetted at 50% moisture content by weight at all times by a wetting system in the primary area.
3. Limited occupant load (i.e. 2 staff present only).
4. Exit travel time study indicates 1.3 minutes.

Dated at Toronto, this 5th day, in the month of October, in the year 1995, for application number 1995-46.

RULING

1. **The Applicant**

   The Bruce County Board of Education is the holder of a permit under the Building Code Act, 1992 to construct a new school (i.e. Amabel-Sauble Community School) at 555 Sauble Falls Parkway, Sauble Beach, Ontario.

2. **Description of Constrution**

   The Amabel-Sauble Community School is a one storey assembly occupancy (i.e. Group A, Division 2) that is provided with a fire alarm system.

   The building contains a two hour fire wall that divides the school into building areas of 1764 m? and 1994 m? respectively.

   The school has a central open pit area in the corridor system. This area consists of a recessed hexagon pit with three risers from the top to the bottom. At the edge of the pit on the level of the corridor fixed benches are to be installed.

   The fixed benches do not reduce the required unobstructed width of the corridor. The fixed benches are intended to provide seating for short periods of time for the students or staff congregating between classes, at recess or lunch hour.

3. **Dispute**

The dispute between the Applicant and Respondent concerns sufficiency of compliance with the technical requirements of Clause 3.3.2.5.(1)(a) of the Building Code. At issue is whether a central open area of the corridor system that includes a recessed hexagon pit with fixed benches is required to be separated from the aisle space that surrounds all 6 sides by a 45 minute fire separation.

4. **Provision of the Building Code**

Clause 3.3.2.5.(1)(a) Corridors

1. Corridors used by the public in assembly occupancies as access to exits shall be separated from the remainder of the building by a fire separation having a fire-resistance rating of not less than 1 h, except that
    a. the fire-resistance rating need not be more than 45 min if the fire-resistance rating of the floor assembly is not required to be more than 45 min

5. **Applicant's Position**

There is a central open area of the corridor system that has a recessed hexagon pit surrounded by fixed benches with access aisles spaces on all six sides.

The Applicant submitted that the fixed benches in this central pit area provide seating for short periods of time for students and/or staff congregating between classes, at recess or lunch hour. These benches do not reduce the required unobstructed width of the corridor (i.e. 10 feet wide corridor is maintained around all six sides of the pit benches). The Respondent also submitted that the benches act as a safety barrier to the three steps into the pit which would be a potential hazard if the benches were removed.

The Applicant submitted that the Bruce County Board of Education wishes to have the fixed benches included in the construction of the pit area without a 45 minute fire separation between the pit area and the corridor.

6. **Chief Building Officials Position**

The Respondent submitted that the pit area is being designed as an assembly area with the provision of fixed benches. As this is part of the corridor system of the school, no other occupancy is allowed. The pit area shall be enclosed by a 45 minute fire separation, with doors having self-closing devices.

The Respondent submitted that an alternative would be to remove the fixed benches from this area.

7. **Commission Ruling:**

   It is the decision of the Building Code Commission that the central open area of the corridor system that includes a recessed hexagon pit with fixed benches provides sufficiency of compliance with the requirements of the Building Code as this space is not considered an assembly occupancy, subject to the following conditions:

   1. The open pit area is used as a temporary overflow space only (i.e. students and/or staff congregating between classes, at recess or lunch hour).
   2. No furniture or furnishings are permitted to be used in this area.

8. **Reasons:**
   1. The required exit width is not reduced by the open pit area.
   2. The travel distance from the open pit to the exits meets the Building Code requirements.
   3. The design intent is that this open area forms part of the corridor system, and is not intended for use as an assembly occupancy.

Dated at Toronto, this 5th day, in the month of October, in the year 1995, for application number 1995-43.

RULING

1. **The Applicant**

   Mr. Daniel Chew, Calvary Bible-Presbyterian Church is an applicant for a permit under the Building Code Act, 1992 to install a residential cook top and exhaust system in the kitchenette area of the recreation hall of the Church at 3065 Ridgeway Drive, Mississauga, Ontario.

2. **Description of Constrution**

   The subject Church includes an area where household cooking equipment will been installed for the purpose of conducting cooking demonstrations. The stove will also be used for warming foods, and coffee and tea preparation. Commercial type cooking will not be permitted.

3. **Dispute**

   The dispute between the Applicant and Respondent concerns sufficiency of compliance with the technical requirements of Article 6.2.2.6. of the Building Code. At issue is whether the requirements of NFPA-96, "Installation of Equipment for the Removal of Smoke and Grease-Laden Vapours from Commercial Cooking Equipment" need be applied to the residential cooking equipment being used for the purpose of conducting cooking demonstrations.

4. **Provision of the Building Code**

Article 6.2.2.6. Commercial Cooking Equipment

Systems for the ventilation of restaurant and other commercial cooking equipment shall be designed, constructed and installed to conform to NFPA-96, "Installation of Equipment for the Removal of Smoke and Grease-Laden Vapours from Commercial Cooking Equipment", except as required by Sentences 3.5.3.1.(1) and Article 3.5.4.2.

5. **Applicant's Position**

The Applicant submitted that residential cooking equipment is being proposed for the purpose of conducting cooking demonstrations.

The Applicant submitted that the proposal to use a residential cook top and exhaust was turned down on the basis that grease laden vapours produced by the proposed use would create a hazard of significant measure to warrant the use of a commercial exhaust system employing a fire suppression system. It is the Applicant's position that the production of grease vapours would be so minimal as to render an insignificant threat to fire safety for the following reasons:

a. The maximum frequency of cooking classes would be once a month.
b. Precooked products would be used for the cooking classes.
c. The cooking process would be confined to demonstration purposes of the precooked food and for very small quantity.
d. Cooking classes would be limited to demonstration only by a qualified individual experienced in the preparation and processes involved with the particular demonstration.
e. Attendance to the classes is anticipated to be at most 20 people.
f. No commercial type cooking will be permitted.
g. Food quantities will be restricted to samples which will only be warmed on site and not prepared on site.
h. With the exception of coffee and tea preparation, cooking for assembly of people will not occur.
i. A sign will be posted restricting cooking to: demonstration purposes of precooked food only, warming foods, coffee and tea preparation.

6. **Chief Building Officials Position**

The Respondent submitted that the installation of cooking for the preparation of meals in industrial, commercial or institutional applications requires an exhaust system designed in conformance with NFPA-96.

The Respondent submitted that there have been many formal interpretations issued by the National Fire Protection Association (NFPA) to clarify the scope of NFPA-96. These interpretations confirm that NFPA-96 is applicable to these types of installations and that the Authority Having Jurisdiction should be consulted.

The Respondent also submitted that in similar circumstances over the years it has been found that, once installed, demand as well as the variety of food preparation increases generating a more significant hazard.

7. **Commission Ruling:**

It is the decision of the Building Code Commission that the residential cook top and exhaust system shows sufficiency of compliance with the Building Code provided that:

1. No commercial type cooking is permitted.
2. No more than 20 people are present within the demonstration area at any one time.
3. Use of the stove is restricted to occasional cooking demonstration only attended by trained personnel at all times.
4. A sign will be posted restricting cooking to demonstration purposes of precooked food only warming foods, coffee and tea preparation.
5. Demonstrations are carried out by persons trained in the use of the cooking equipment and fire extinguishers.
6. Fire extinguishers must be located where clearly visible.
7. The stove will be electric.
8. No other stoves or cooking ovens are permitted within the demonstration area.
9. The sprinkler protection in the area must be maintained.

8. **Reasons:**

0. The stove is a residential - type stove.
1. Limited smoke or grease-laden vapours will be produced by the preparation of meals.
2. Cooking is for demonstrations only and is not continuous as in most commercial applications.
3. Only trained personnel will operate the equipment.
4. The area is sprinklered and portable extinguishers will be provided.

Dated at Toronto, this 5th day, in the month of October, in the year 1995, for application number 1995-38.

RULING

1. **The Applicant**

   Mr. Nick Sampogna, 928773 Ontario Inc., is the holder of a permit under the Building Code Act, 1992 to construct a 9 storey building comprising retail commercial occupancy on the ground floor and residential occupancy on the 2nd to 9th floors, at Glen Park Co-Operative Inc., 2495 Eglinton Avenue East, Scarborough, Ontario.

2. **Description of Constrution**

   The project is a 9 storey building comprising retail commercial occupancy on the ground floor and residential occupancy on the 2nd to 9th floors .

   The west exposing building face of the building has a limiting distance of 2050 mm for the first storey (Group E - Retail) and 50 mm for the upper storeys (Group C - Residential).

   A building permit was granted for the subject building on the basis that a Building Materials Evaluation Commission (BMEC) approved Window Sprinkler System would be used on the west exposing building face.

3. **Dispute**

   The dispute between the Applicant and Respondent concerns sufficiency of compliance with the technical interpretation of Article 3.2.3.1. of the Building Code. At issue is whether the limiting

distance required for the west exposing building face may be extended onto an adjoining parcel of vacant land to permit the use of unprotected window openings.

4. **Provision of the Building Code**

Subsection 3.2.3. Spatial Separation and Exposure Protection of Buildings

Article 3.2.3.1. Limiting Distance and Area of Unprotected Openings

1. Except as provided in Articles 3.2.3.9. to 3.2.3.11, the area of unprotected openings shall not be more than that set forth in Tables 3.2.3.A. or 3.2.3.B. for the limiting distance applicable to the exposing building face under consideration.
2. The area of the unprotected openings in an exposing building face shall be the aggregate area of unprotected openings expressed as a percentage of the area of the exposing building face in Tables 3.2.3.A. and 3.2.3.B.(Sentence 3.2.3.2.(1).)
3. For the purposes of determining the type of construction and cladding and the fire-resistance rating of an exterior wall, the exposing building face shall be taken as the projection of the exterior wall onto a vertical plane located so that no portion of the exterior wall of the building or of a fire compartment, if the fire compartment complies with the requirements of Sentence 3.2.3.2.(1), is between the vertical plane and the line to which the limiting distance is measured and, for these purposes, the area of unprotected openings shall be determined from Table 3.2.3.A. or Table 3.2.3.B.
4. For the purposes of determining the actual percentage of unprotected openings permitted in an exterior wall, the location of the exposing building face is permitted to be taken at a vertical plane located so that there are no unprotected openings between the vertical plane and the line to which the limiting distance is measured.
5. Where fire fighting facilities cannot reach the building within 10 min of the alarm being received, the limiting distance shall be doubled.

5. **Applicant's Position**

The Applicant submitted that there is an open space to the west of the subject property that establishes sufficient distance from adjacent townhouses to permit unprotected window openings in the nine storey building.

The Applicant proposed to use the adjoining property to increase the limiting distance from the west exposing building face.

6. **Chief Building Officials Position**

   The Respondent submitted that a building permit was issued on the basis of a Building Materials Evaluation Commission (BMEC) approved Window Sprinkler System being used for the window openings in the west exposed building face. The applicant is now proposing to delete this system and use an adjoining property to increase the limiting distance, since at the present time this parcel of land is vacant.

   The Respondent does not agree with the Applicants proposal since the definition of limiting distance requires the distance to be measured to the property line (not to infringe on adjoining property owners rights). The Respondent submitted that when a building permit application is processed, the Building Code is applied to the building under that application. The Building Code cannot control what is or is likely to be built on adjoining land in the future. The adjoining owner has the right to measure the limiting distance to the property line and construct any future building accordingly.

7. **Commission Ruling:**

   It is the decision of the Building Code Commission that not providing protected window openings on the west building face does not comply with the requirements of the Building Code.

8. **Reason:**

   No evidence was provided that the adjacent property owner was prepared to enter into an agreement with the applicant, registering on title of both properties the existing spatial separation between buildings and thereby allowing the spatial separation to be calculated as if the buildings were constructed on the same property.

Dated at Toronto, this 19th day, in the month of September, in the year 1995, for application number 1995-39.

BCC Ruling No. 95-42-462

BUILDING CODE COMMISSION DECISION ON B.C.C. #95-42-462

IN THE MATTER OF Subsection 24(1) of the *Building Code Act, 1992.*

RULING

1. **The Applicant**

   Mr. Jim Vecia, Roseland Foods is the holder of a permit under the Building Code Act,1992 to construct a 81 m² (871.9 ft²) addition to a 507.1 m² (5458.6 ft²) suite in an existing strip plaza at, Roseland Foods, 3015 New St., Burlington, Ontario.

2. **Description of Constrution**

   The subject building is a one storey unsprinklered combustible mercantile strip plaza that contains 6 suites located between two existing fire walls.

   The building area (i.e. between existing firewalls) is 1710 m² (18406.9 ft²). The construction of an unsprinklered 81 m² (871.9 ft²) storage addition is proposed for the 507.1 m² (5458.6 ft²) Roseland Foods suite.

3. **Dispute**

   The dispute between the Applicant and Respondent concerns sufficiency of compliance with the technical interpretation of Article 3.2.2.44. of the Building Code. At issue is whether not providing a sprinkler system for the addition to one of 6 units in an existing unsprinklered mercantile strip plaza will provide sufficiency of compliance with Article 3.2.2.44. of the Ontario Building Code

4. **Provision of the Building Code**

Article 3.2.2.44. Mercantile Buildings, up to 3 Storeys

1. A building classified as Group E shall conform to Sentence (2) provided the building
   a. is not more than 3 storeys in building height, and
   b. has a building area not more than the value in Table 3.2.2.M.
2. The building shall be of combustible or noncombustible construction used either singly or in combination, and
   a. floor assemblies shall be fire separations with a fire-resistance rating of not less than 45 min,
   b. mezzanines shall have, if of combustible construction, a fire-resistance rating of not less than 45 min,
   c. roof assemblies shall have a fire resistance rating of not less than 45 min,except that in buildings not more than 1 storey in building height, the fire-resistance rating is permitted to be waived provided the roof assembly is of noncombustible construction or is constructed as a fire-retardant treated wood roof system conforming to Article 3.1.14.1., and
      i. if unsprinklered, the building area is not more than 1 500 m² (16,100 ft²), and
      ii. if sprinklered, the building area is not more than
      iii. 2 400 m² (25,800 ft²) if facing 1 street,
      iv. 3 000 m² (32,300 ft²) if facing 2 streets, or
      v. 3 600 m² (38,800 ft²) if facing 3 streets,
   d. all loadbearing walls, columns and arches supporting an assembly required to have a fire-resistance rating shall have a fire-resistance rating of not less than 45 min or shall be of noncombustible construction, except that such

      members and assemblies supporting a fire separation shall have a fire-resistance rating not less than that required for supported assembly.

5. **Applicant's Position**

The Applicant submitted that the requirements to sprinkler the new proposed addition are excessive and should not be required since the existing building construction does not conform to Article 3.2.2.44. of the Building Code.

The Applicant also submitted that creating a smaller building area by constructing a firewall between the existing suite (i.e. Roseland Foods) and the proposed addition is not feasible.

6. **Chief Building Officials Position**

   The Respondent submitted that the Building Code requirement for a sprinkler system is quite clear. Also, the Building Code does not provide any exception to the requirements for a sprinkler system in this case.

7. **Commission Ruling:**

   It is the decision of the Building Code Commission that not providing a sprinkler system in the addition to one of six units in the existing unsprinklered mercantile strip plaza will provide sufficiency of compliance with Article 3.2.2.44. of the Building Code provided that the addition is separated from the existing building by a 2 hour fire separation.

8. **Reasons:**
   1. The addition is only 81 m² or approx. 5% of the building area.
   2. Access is provided for fire-fighting purposes to 2 faces of the building.
   3. Existing occupancies are separated by 200 mm (8") concrete block party walls.

Dated at Toronto, this 19th day, in the month of September, in the year 1995, for application number 1995-40.

Chief Building Official
Town of Grimsby
The Respondent

RULING

1. **The Applicant**

   Orchardview Village Inc. is the holder of a permit under the Building Code Act, 1992 to construct a 16 unit residential townhouse condominium, at Orchardview Townhomes, 165 Main Street East, Grimsby, Ontario.

2. **Description of Constrution**

   The building under dispute is a 16 unit townhouse condominium with self-contained heating and mechanical ventilation systems. Each unit has a fan assisted combustion gas furnace utilizing a Type "B" vent assembly and a direct vent water heater.

3. **Dispute**

   The dispute between the Applicant and Respondent concerns sufficiency of compliance with the technical interpretation of Article 9.32.3.1. of the Building Code. At issue is whether the dwelling units should be categorized as "Type III" which requires the mechanical ventilation system to be designed under Part 6 of the Building Code.

4. **Provision of the Building Code**

   Article 9.32.3.1. General

   1. For the purposes of this Subsection a non-solid fuel-fired appliance shall be classified as

a. direct vented whereby the combustion air is supplied directly from the outdoors to the combustion chamber via a sealed passageway, and the products of combustion are exhausted directly outdoors through an independent sealed vent,
b. mechanically vented induced draft whereby combustion air is supplied from within the building envelope and the products of combustion are positively conveyed to the outdoors by means of a dedicated sealed vent, or
c. atural draft whereby combustion air is supplied from within the building envelope and the products of combustion are conveyed to the outdoors through a chimney or Type B vent.

2. For the purposes of this Subsection a dwelling unit shall be categorized as
   a. Type I when
      i. all fuel-fired combustion appliances located in the dwelling unit are direct vented or except for fireplaces, are mechanically vented induced draft, and
      ii. the dwelling unit does not contain a solid fuel- fired combustion appliance,
   b. Type II when a solid fuel-fired combustion appliance is installed in a Type I dwelling unit,
   c. Type III when a mechanically vented induced draft non- solid fuel-fired fire-place or a natural draft appliance is present, or
   d. Type IV when electric space heating is present.

5. **Applicant's Position**

The Applicant submitted that the initial submission for a permit was for a mid efficient furnace with sidewall venting and a direct vent water heater. During 1994 the use of sidewall vent material was discontinued because of problems. At additional expense the builder elected to use a Type "B" vent system for the furnace and still keep the direct vent water heater. The Applicant submitted that this falls within the category of a Type I house since the furnace is a positive venting induced draft type, and the hot water tank is direct vented.

The Applicant submitted that none of these appliances are classified as natural draft. The Applicant also submitted that connecting a mechanically vented induced draft furnace to a Type "B" vent does not change the furnace to a natural draft. It does not have a draft diverter which negates the possibility of spillage.

The Applicant submitted that the furnace is listed by the manufacturer with Canadian Gas Association (CGA) as Type I category using a Type "B" vent. The Applicant also submitted that

the gas utilities have verified the equipment, installation, listing, manufacturers and Code requirements.

6. **Chief Building Officials Position**

The Respondent submitted that Building Code classifies a non-solid fuel-fired furnace utilizing a Type "B" vent for conveying products of combustion as a natural draft appliance and therefore, the dwelling is categorized as Type III. The mechanical ventilation system of a Type III dwelling must be designed and installed in accordance with Part 6 of the Building Code.

The Respondent submitted that in order to determine the design criteria for a residential mechanical ventilation system the fuel-fired appliances must be classified as either direct vented, mechanically vented induced draft or natural draft as defined in Sentence 9.32.3.1.(1) of the Building Code. Once all the appliances are classified, the dwelling unit type must be categorized as per Sentence 9.32.3.1.(2). (i.e. Type I, II, III or IV).

The mechanical ventilation system shall be designed under Part 6 of the Building Code, however, in a Type I, II and IV dwelling unit, Subsection 9.32.3. may be used.

The Respondent also submitted that the furnace installation in all units at the subject property utilizes a Type "B" vent to convey the products of combustion to the outdoors. This installation classifies the furnace as a natural draft appliance based on Sentence 9.32.3.1.(1)(c). The presence of a natural draft appliance categorizes the dwelling units as Type III as per Sentence 9.32.3.1.(2)(c), therefore, the mechanical ventilation system shall be designed under Part 6 of the Building Code.

The Respondent submitted that the initial submission for a building permit was based on a mechanically vented induced draft furnace with sidewall venting and a direct vent water heater. These appliance classes would categorize the dwelling units as Type I and permit a Part 9 mechanical ventilation design. The contractor took the liberty of changing this installation to one incorporating a Type "B" vent without prior written authorization of the Chief Building Official.

7. **Commission Ruling:**

It is the decision of the Building Code Commission that the dwelling units are categorized as Type III dwellings as defined in Article 9.32.3.1. of the Building Code which requires the mechanical ventilation system to be designed under Part 6 of the Building Code.

8. **Reason:**

   The installed Type "B" vent is not considered a dedicated sealed vent that positively conveys products of combustion to the outdoors.

Dated at Toronto, this 22th day, in the month of August, in the year 1995, for application number 1995-37.

RULING

1. **The Applicant**

   Mr. Peter Clewes, Wallman, Clewes, Bergman Architect Ltd. is an applicant for a permit under the Building Code Act, 1992 to construct a two storey mixed use commercial building at 4300 Steeles Avenue East, Markham, Ontario.

2. **Description of Constrution**

   The applicant is proposing to construct a two storey mixed use commercial building. The proposed building has a building area of 15,600 m². The main and second floors will be interconnected. The main floor will contain a market style retail layout and the 7,200 m² second floor will contain restaurants. The two basement levels will contain parking and small storage and service rooms.

   Each unit on the main floor will face a circulation aisle either 3 m or 5 m wide and at least one 2-1/2 m cross aisle, with no fire separation between units nor between units and circulation and cross aisles (i.e. similar to a department store). Each unit location has been sold as a condominium.

   Partitions between units will range from 2.4 to 3 m in height. A security grill will be provided between units and circulation aisles permitting a view into units after business hours. The top of the unit will either be open or have an egg-crate type ceiling.

   The entire building perimeter will face fire access routes, although the Building Code requires only 50 percent of this building perimeter to face a fire route.

The fully sprinklered building will have a fire alarm and detection system, emergency lighting system, and smoke exhaust system for the ground floor. The fire alarm system will be monitored by an independent central station. The sprinkler system will be designed to function as part of the required fire detection system. A standpipe and hose system is proposed for the two basement levels.

3. **Dispute**

The dispute between the Applicant and Respondent concerns sufficiency of compliance with the technical interpretation of Article 3.2.9.1. of the Building Code. At issue is the installation of a standpipe and hose system in the two basement levels only and not throughout the two storey building.

4. **Provision of the Building Code**

Article 3.2.9.1. Requirement for Standpipe and Hose Systems

Except as provided in Article 3.2.9.2., a standpipe and hose system shall be installed in every building that:

a. is more than
   i. 3 storeys in building height, or
   ii. 14 m in height measured between grade and the ceiling of the uppermost storey,
b. is greater in building area than the area shown in Table 3.2.9.A. for the applicable building height shown in the Table where the building
   i. is not sprinklered, and
   ii. is not more than 14 m high measured between grade and the ceiling of the top storey, or
c. contains more than one storey below grade.

5. **Applicant's Position**

The Applicant submitted that Subclause 3.2.9.1.(1)(b)(ii) of the 1990 edition of the Building Code (O.Reg. 413/90) requires a standpipe and hose system in every basement of a building that has more than one storey below grade. Based on the 1990 Building Code, a standpipe system would only be required in the two basement levels of the building.

The Applicant submitted that Clause 3.2.9.1.(1)(c) of the 1993 Building Code (O.Reg. 158/93) requires a standpipe and hose system to be installed in every building that contains more than one storey below grade. Based on the 1993 Building Code, a standpipe and hose system would be required throughout the proposed building.

The Applicant submitted a letter dated February 3, 1994 by the Housing Development and Building Branch, Ministry of Housing that clarifies the interpretation of Article 3.2.9.1. with respect to the requirements of a standpipe and hose system in the basement. The Ministry confirmed that the wording in the Article 3.2.9.1. of the current edition was an oversight they intended to correct in the next edition of the Code. Also, the Applicant submitted that the Office of the Fire Marshall of Ontario agreed with this interpretation and has no objection to the original wording being reinstated. Therefore, the Respondent maintained that it was never the Code writers intention that a standpipe and hose system be installed in storeys above grade as a result of being required below grade.

The Applicant submitted that despite the wording in the current edition of the Building Code, a standpipe and hose system should not be required for the first and second storeys of the fully sprinklered two storey building.

6. **Chief Building Officials Position**

The Respondent submitted that the language of the Building Code is quite clear. Clause 3.2.9.1.(1)(c) states that a standpipe and hose is required for every building that contains more than one storey below grade. Since the Pacific Mall building contains more than one storey below grade, a standpipe and hose system must be provided throughout the entire building.

The Respondent also submitted that the Pacific Mall building was the subject of a previous Building Code Commission Hearing. It is not clear what value if any, was placed on the existence of a standpipe and hose system in leading the Commission to decision # 94-14-392 rendered on May 31, 1994.

The Respondent submitted that in the aforementioned Ruling the Commission permitted the retail floor areas to remain open and uninterrupted by fire separations presumably on the basis of the floor area being sprinklered and for the reasons given. The Fire Department has serious concerns about their ability to be able to control and fight a fire within such a large open area (202 m by 93 m) with high ceilings (up to 10 m) and no internal means of connecting hoses. As a result of this concern, the Fire Department inserted a clause in the site plan agreement, executed

by the owner (Pacific Mall Developments Inc.) and the Town of Markham, to provide a standpipe and hose system throughout the building. Through this agreement the owner agreed to provide such a system.

7. **Commission Ruling:**

   It is the decision of the Building Code Commission that providing a standpipe and hose system for the two basement levels only provides sufficiency of compliance with Article 3.2.9.1. of the Building Code.

8. **Reason:**

   The Housing Development and Buildings Branch, Ministry of Municipal Affairs and Housing confirmed that the present wording in Article 3.2.9.1. of the Building Code is an editorial oversight and will be corrected to reflect the wording in Article 3.2.9.1. of the Revised Regulation of Ontario 1990, Regulation 61.

Dated at Toronto, this 24th day, in the month of August, in the year 1995, for application number 1995-34.

RULING

1. **The Applicant**

   Mr. Don Duncan, C.E.O., Guelph YMCA-YWCA is the holder of a permit under the Building Code Act, 1992 to construct a YMCA-YWCA comprising a childcare area, recreation area and gymnasium with an interconnected floor space at 130 Woodland Glen Drive., Guelph, Ontario.

2. **Description of Constrution**

   The portion of the project subject to the dispute is a basement gymnasium with an interconnected floor space at ground level. The second floor (i.e. ground level) is one large open exercise area that is interconnected with the gymnasium below.

   The space is sprinklered and has direct exit to grade from the upper (ground) floor level and lower (basement) floor level. It also has two open stairs between the floor levels (one at each end).

3. **Dispute**

The dispute between the Applicant and Respondent concerns whether the means of egress from the gymnasium and exercise space provides sufficiency of compliance with the Building Code. At issue is whether the an open stair between the floor areas may be used as an exit.

4. **Provision of the Building Code**

Article 3.4.2.1. Minimum Number of Exits

1. Except as provided in Sentences (2) to (4), and (6), every floor area as regulated in Article 3.4.1.1. shall be served by not less than 2 exits.
2. In building not more than 2 storeys in building height, a floor area is permitted to be served by one exit provided the floor area and travel distance requirements conform to Table 3.4.2.A. and the total occupant load served by the exit is not more than 60.
3. Except as provided in Sentence (4), where a single exit is permitted in Sentence (2) from a floor area classified as Group B or Group C occupancy, the exit shall be an exterior doorway not more than 1.5 m (4 ft 11 in) above adjacent ground level.
4. A floor area containing only dwelling units having access to exit conforming to Sentences 3.3.4.4.(1) to (4) need not comply with Sentence (1).
5. Exits are not required directly from roof top-enclosures that are provided with access to exit in conformance with Sentences 3.3.1.3.(5) and (6).
6. Every room containing an assembly occupancy serving a hotel, and located in the building containing the hotel, shall be provided with not less than
    a. 3 separate egress doorways from the room where the occupant load is more than 600 persons, and
    b. 4 separate egress doorways from the room where the occupant load is more than 1000 persons.
7. Each egress doorway in Sentence (6) shall be considered as contributing not more than
    a. one third of the required width where 3 egress doorways are required, and
    b. one fourth of the required width where 4 egress doorways are required.

Article 3.4.4.1. Fire-Resistance Rating of Exit Separations

8. Except as provided in Article 3.4.4.3. and Sentences (2), 3.3.5.5.(3) and 3.4.4.2.(2), every exit shall be separated from each adjacent floor area by a fire- separation having a fire-resistance rating not less than that required for the floor assembly above the floor area and, where there is no floor assembly above, not less than that required by Subsection

3.2.2. for the floor assembly below, but in no case shall the fire-resistance rating be less than 45 min.

9. The fire-resistance rating of the fire separation in Sentence (1) need not be more than 2 h.
10. Where an exit stair in an assembly hall or theatre serves more than one balcony level, the exit stair shall be separated from the remainder of the building in conformance with Sentence (1).

5. **Applicant's Position**

The Applicant submitted that the gymnasium and overlooking exercise equipment area is one large open floor space that is supervised by staff. The floor levels are completely open separated only by railings.

The Applicant also submitted that the Building Department is asking for an exit stair with a fire separation and an additional exterior door. This would obstruct supervision and provide security concerns. The Applicant submitted that adequate means of egress are provided via the two interconnecting stairs between the floor levels.

6. **Chief Building Officials Position**

The Respondent submitted that the gymnasium is located in the basement floor area. Article 3.4.2.1. requires every floor area to be served by not less than 2 exits except for exemptions with respect to size of floor area, travel distance, and maximum occupant load.

The Respondent submitted that the basement floor area is 733 m², exceeds 15 m travel distance, and has an occupant load exceeding 60 persons. Therefore two exits are required.

The Respondent submitted that Article 3.4.4.1. requires an exit to be separated from each of the floor areas with a ½ hr rated fire separation.

The Respondent also submitted that the reason for non-acceptance of the Applicant's proposal is that it does not comply with the Building Code.

7. **Commission Ruling:**

It is the decision of the Building Code Commission that the current exit design from the basement gymnasium does not provide sufficiency of compliance with Article 3.4.2.1. and Article 3.4.4.1. of the Building Code.

8. **Reasons:**
    1. The floor area of the basement gymnasium required that a minimum of 2 exits must be provided.
    2. If any exit is required through the first floor, the exit from the basement gymnasium must be separated by fire separation as required by Article 3.4.4.1.

Dated at Toronto, this 3rd day, in the month of August, in the year 1995, for application number 1995-36.

For the Respondent

RULING

1. **The Applicant**

   The majority of the subject building is leased by White Rose Craft and Nursery Sales Limited from the Wellington County Roman Catholic Separate School Board for retailing purposes. A building permit (No. 95-00232) has been issued under the Building Code Act, 1992 to construct a greenhouse type addition to an existing building at 265 Edinburgh Road North, Guelph, Ontario.

2. **Description of Constrution**

   The existing 3035 m² single storey masonry building contains two occupancies. White Rose Craft and Nursery Sales Limited occupies 2480 m² and the Wellington County Roman Catholic Separate School Board occupies 55 m² for the storage of maintenance equipment. The building is protected by a fire alarm and sprinklering system.

The Applicant has constructed a new unsprinklered 562 m² greenhouse addition with the gables flashed to the main building. The proposed new addition is required to be sprinklered in accordance with the NFPA-13 standard. This is based on the general Size and Occupancy requirements for fire safety regulated by Article 3.2.2.44. of the Building Code. The greenhouse is separated from the existing building by a 250 mm (10 inch) thick concrete block wall. Direct access is provided from the existing building into the greenhouse. The construction of the greenhouse provides complete ease of egress from the greenhouse in the event of a fire. The greenhouse has a tempered glass roof and except for three 12' sections, there are no permanent exterior nor interior walls.

3. **Dispute**

The dispute between the Applicant and Respondent concerns the technical interpretation of Article 4.3.6.1. of the Building Code, and sufficiency of compliance with the technical interpretation of Article 3.2.2.44. and Sentences 3.2.2.12.(1) and 3.2.5.13.(1) of the Building Code. At issue is the determination of the following two matters: (1) whether the glass on the greenhouse roof must comply with CAN\CGSB-12.20-M, "Structural Design of Glass for Buildings"; and (2) whether a sprinkler system is required in a greenhouse addition to an existing mercantile occupancy.

4. **Provision of the Building Code**

Article 4.3.6.1. Glass

Glass shall be designed in conformance with CAN\CGSB-12.20-M, "Structural Design of Glass for Buildings".

Article 3.2.2.44. Mercantile Buildings, up to 3 Storeys

1. A building classified as Group E shall conform to Sentence (2) provided the building
    a. is not more than 3 storeys in building height, and
    b. has a building area not more than the value in Table 3.2.2.M.
2. The building shall be of combustible or noncombustible construction used either singly or in combination, and
    a. floor assemblies shall be fire separations with a fire-resistance rating of not less than 45 min,

b. mezzanines shall have, if of combustible construction, a fire-resistance rating of not less than 45 min,
c. roof assemblies shall have a fire resistance rating of not less than 45 min, except that in buildings not more than 1 storey in building height, the fire- resistance rating is permitted to be waived provided the roof assembly is of noncombustible construction or is constructed as a fire-retardant treated wood roof system conforming to Article 3.1.14.1., and
    i. if unsprinklered, the building area is not more than 1 500 m² (16,100 ft²), and
    ii. if sprinklered, the building area is not more than 2 400 m² (25,800 ft²) if facing 1 street, 3 000 m? (32,300 ft²) if facing 2 streets, or 3 600 m² (38,800 ft²) if facing 3 streets,
d. all loadbearing walls, columns and arches supporting an assembly required to have a fire-resistance rating shall have a fire-resistance rating of not less than 45 min or shall be of noncombustible construction, except that such members and assemblies supporting a fire separation shall have a fire-resistance rating not less than that required for supported assembly.

Sentence 3.2.2.12.(1) Sprinklers in Lieu of Roof Rating

3. The requirements in Articles 3.2.2.16. to 3.2.2.62. for roof assemblies to have a fire-resistance rating are permitted to be waived provided
    a. the building is sprinklered,
    b. the sprinkler system in Clause (a) is electrically supervised in conformance with Sentence 3.2.4.16.(5), and
    c. the operation of the sprinkler system in Clause (a) will cause a signal to be transmitted to the fire department in conformance with Sentence 3.2.4.7.(3).

Sentence 3.2.5.13.(1) Automatic Sprinkler System

4. Except as provided in Sentences (2) and (3), where a sprinkler system is required, it shall be designed, constructed, installed and tested in conformance with NFPA 13, "Installation of Sprinkler Systems".

5. **Applicant's Position**

The Applicant submitted that Appendix A of CAN\CGSB-12.20-M references the Commentary on Glass Design in Chapter 4 of the Supplement to the National Building Code 1990. The

commentary states that "Where special circumstances such as sloped or overhead glazing give rise to unusual hazards, such as increased risk of injury to occupants of the general public, the provision of safety glass may be required." The Applicant stated that it always accepted this as a requirement, thus the glass installed on this project is 4 mm tempered glass (e.g. manufactured labelled safety glass). The Applicant submitted that CAN\CGSB-12.20-M does not cover greenhouses. The subject Standard states that it is not intended to be used for glass employed in greenhouses. The Applicant further submitted that there is much precedence for this by the acceptance of similar projects by other building departments throughout the Province. The Applicant submitted that the requirement to sprinkler the greenhouse is excessive and should not be required in this instance for the following reasons:

1. The main building is fully sprinklered in compliance with the Building Code.
2. The greenhouse is accessory and subordinate to the Occupant's main use and the volume of people will be far less than in the main building.
3. The building/greenhouse arrangement was not contemplated when the subject Building Code regulation was being developed.
4. The purpose of the greenhouse is to provide an area of protective covering for plants and therefore the goods offered for sale to the public are non-combustible.
5. The nature of the greenhouse construction allows complete ease of access/egress to the public in the event the need to exit the greenhouse should ever arise.
6. The greenhouse is composed of a tempered glass roof. Except for three 12'- 0' sections, there are no permanent exterior nor interior walls.
7. The structure will not be used year round. Sprinkler or any other systems will be frozen over the winter months and will be affected by the elements.

6. **Chief Building Officials Position**

The Respondent submitted that Article 4.3.6.1. of the Building Code requires compliance with CAN/CGSB-12.20-M89. The Standard requires protection for the public such as laminated glass, wired glass or other measures. The Supplement of the National Building Code also requires safety glass for public protection. The Respondent submitted that the reason for not accepting the Applicant's proposal is that the CAN/CGSB-12.20-M89 Standard only exempts greenhouses not occupied by the public. This facility is used as a retail area and may have a high occupant load. The Respondent addressed the requirement to sprinkler the greenhouse addition as follows:

1. The building is required to be sprinklered in conformance Article 3.2.2.44. The greenhouse is an extension of the main building and therefore must be sprinklered due to

the total building area and the waiving of fire protection of the roof assembly as set out in Article 3.2.2.44. and Sentence 3.2.2.12.(1) respectively.

2. NFPA 13 requires sprinkler protection below noncombustible canopies that contain combustible storage.

7. **Commission Ruling:**

It is the decision of the Building Code Commission that not providing sprinklering for the greenhouse provides sufficiency of compliance with the Building Code provided

a. an annual permit be obtained as required if the structure was temporary in nature, reconfirming its use for the display and sale of horticultural products; and
b. combustible storage be limited and considered as outdoor public storage under the Fire Code for exposure hazard.

It is also the decision of the Building Code Commission that the tempered glass used on the sloping roof does not provide sufficiency of compliance with the Building Code.

8. **Reasons:**

0. The unheated structure is used seasonally.
1. The structure is non-combustible construction.
2. The unenclosed greenhouse provides unlimited means of egress.
3. The existing building is sprinklered and is separated from the greenhouse by masonry walls.
4. Fire-spread through unprotected openings is addressed through the combustible storage provisions of the Fire Code.
5. The proposed structure of mercantile use is not a low human occupancy building as described in CAN/CGSB-12.20 -M89 Structural Design of Glass for Buildings as referenced in Part 4 of the Building Code.
6. CAN/CGSB-12.20-M89 does not permit the use of tempered glass alone for sloped glazing and skylights since no restraining system is provided to prevent glass particles from falling in the event of glass breakage.

Dated at Toronto, this 3rd day, in the month of August, in the year 1995, for application number 1995-34.

RULING

1. **The Applicant**

   Van Con General Contractors Ltd. is the holder of a permit under the Building Code Act, 1992 to construct a 6 storey noncombustible residential building containing 39 apartment units, at Parkside Place, 72 Woodlawn Rd. East, Guelph, Ontario.

2. **Description of Constrution**

   The structure is a six storey building of non-combustible construction and is designed under Article 3.2.2.37 of the Building Code. Each floor has a maximum of seven two bedroom suites, and is served by two exit stairs. The building has a zoned single stage fire alarm system. Fire detection devices are located in common areas and individual suites. The individual suite air handlers are interlocked to shut down upon activation of the fire detection devices. The garbage and storage areas of the building are sprinklered. The water supply booster pump and emergency/exit lights are powered by a diesel generator. Three sides of the building are accessible to fire department vehicles.

The building plumbing system has been constructed of PVC materials incorporating special fire-stop devices ("doughnuts") at fire separations, and of cast-iron or copper materials with fire stops at fire separations. Where these materials are used together, the PVC is enclosed in a fire resistant wall assembly. The construction of the plumbing system meets with the approval of the local building department. The use of "ABS" piping is limited to only the kitchen and bathroom trap assemblies in each of the 39 unit apartments.

3. **Dispute**

The dispute between the Applicant and Respondent concerns sufficiency of compliance with the technical interpretation of Article 3.1.5.1. & Clause 3.1.5.15.(1)(a) of the Building Code. At issue is the determination of whether the use of combustible pipe traps (i.e. ABS material) servicing basins and sinks in a 6 storey noncombustible residential building will provide sufficiency of compliance with the flame spread rating requirements of the Building Code.

4. **Provision of the Building Code**

Article 3.1.5.1. Noncombustible Materials

Except as permitted in Articles 3.1.5.2. to 3.1.5.21., 3.1.13.4. and 3.2.2.13., where a building or part of a building is required to be of noncombustible construction, the construction shall be made from noncombustible materials.

Clause 3.1.5.15.(1)(a) Combustible Piping Materials

1. Except as permitted in Clause 3.1.5.2.(1)(e), Sentence (2) and Article 3.1.5.20., combustible totally enclosed raceways, piping and tubing and associated adhesives are permitted to be used in a building required to be of noncombustible construction provided they
    a. have a flame-spread rating of not more than 25, except when concealed in a wall or a concrete floor slab.

5. **Applicant's Position**

The Applicant submitted that the "ABS" plumbing trap material be retained since:

1. The amount of combustible "ABS" material is limited to a very small portion of the overall plumbing system.

2. The combustible "ABS" material is minor in comparison to other materials and contents of the apartment.
3. The traps are typically filled or partially filled with water.

6. **Chief Building Officials Position**

The Respondent submitted that all kitchen sink, washroom basin and laundry tub traps and associated piping connecting the fixtures to the DWV system are "ABS" material.

The Respondent also submitted that in accordance with Article 3.2.2.37. of the Building Code the building must be of noncombustible construction. Subsection 3.1.5. regulates the use of combustible materials in buildings required to be noncombustible construction. Clause 3.1.5.15.(1)(a) permits combustible piping to be used in a building required to be of noncombustible construction if it has a flame spread rating not more than 25. "ABS" piping has a flame spread rating of 165-230.

The Respondent submitted that the Applicant's proposal does not comply with the Building Code.

7. **Commission Ruling:**

It is the decision of the Building Code Commission that the use of "ABS" traps in piping in a non-combustible six storey building does not provide sufficiency of compliance with the Building Code.

8. **Reasons:**
    1. No evidence was provided that the "ABS" piping provides a flame-spread of 25 as required by Clause 3.1.5.15.(1)(a) of the Building Code.
    2. The "ABS" traps are not considered as minor components as described in 3.1.5.2.(1)(h) of the Building Code.

Dated at Toronto, this 3rd day, in the month of August, in the year 1995, for application number 1995-33.

For the Respondent

RULING

1. **The Applicant**

   Mr. Carl Quenneville is the holder of a permit under the Building Code Act, 1992 to construct alterations to suite 210 at 1900 Minnesota Court, Mississauga, Ontario.

2. **Description of Constrution**

   The project is located in a two storey fully sprinklered office building in which a glass wall and doors were built, closing in the leased area from a "common" area. The location and geometry of this wall is such that the manual pull station, serving the required exit which is equipped with an electromagnetic locking device, is actually located 1500 mm from the exit, whereas, the Building Code requires such a pull station to be located not more than 600 mm from the door.

3. **Dispute**

   The dispute between the Applicant and Respondent concerns sufficiency of compliance with the technical interpretation of clause 3.4.6.15.(4)(c) of the Building Code. At issue is the determination of whether a manual pull station for a fire alarm system incorporating electromagnetic locking devices, located 1500 mm from an exit will provide sufficiency of compliance with the Building Code.

4. **Provision of the Building Code**

   Clause 3.4.6.15.(4)(c) Door Release Hardware

4. An electromagnetic locking device that does not incorporate latches, pins or other similar devices to keep the door in the closed position is permitted to be installed on an exit door, other than an exit door serving an elementary or secondary school or leading directly from a Group F, Division 1 occupancy
    a. if a manual pull station for the fire alarm system is located on the wall not more than 600 mm (23¾ in) from the door

5. **Applicant's Position**

The Applicant submitted that the subject space was leased effective August, 1994. Substantial expenditures were undertaken by Russel Metals to build out the space including the installation of a glass wall and doors of 16' feet closing our space from the common area.

The Applicant also submitted that the fire alarm pull station nearest to our front door is mounted at where the glass wall meets the nearest partition, being approximately 1,500 mm (59") from the door jamb. This distance extends by 900 mm the above quoted regulations.

The Applicant submitted that the ambient area adjacent to the door is unobstructed by any walls or furniture, in keeping with the open concept plan which utilizes the full glass wall and doors. Consequently, the Applicant does not feel a safety hazard is created by the subject non-conformance. Further, the cost to rectify the subject non-conformance would be very significant.

6. **Chief Building Officials Position**

The Respondent submitted that Clause 3.4.6.15.(4)(c) of the Building Code states "an Electromagnetic lock can be installed, if a manual pull station for the fire alarm system is located on the wall not more than 600 mm, from the door". The present pull station is located 1500 mm from the door and therefore, doors do not meet the Building Code for easy access in an emergency. The Respondent stated that the 1500 mm distance is too far away from the door for a person to reach in a panic situation.

7. **Commission Ruling:**

It is the decision of the Building Code Commission that the location of the manual pull station to release the electromagnetic locking device provides sufficiency of compliance with the Building Code, subject to the following conditions:

4. The signage required under Clause 3.4.6.15.(4)(e) shall also indicate the location of the pull station. The size of the signage shall be in conformance with Clause 3.4.6.15.(4)(f) of the Building Code.
5. Emergency lighting be provided to illuminate the area where the pull station is located.
6. Emergency procedures be reviewed and or amended to ensure occupants are aware of the action necessary to exit the floor area.
7. The space between the doors and the pull station shall remain unobstructed at all times.

8. **Reasons:**
    0. The building is protected by an automatic sprinkler system.
    1. The occupancy is a Business and Personal Service Occupancy "Group D".
    2. The doors are not secured during the normal operating hours.
    3. Staff are aware of the method used to release the door after regular business hours.

Dated at Toronto, this 18th day, in the month of July, in the year 1995, for application number 1995-31.

RULING

1. **The Applicant**

   Mr. Mark Twardowski is an applicant for a permit under the Building Code Act, 1992 to construct a Junior Kindergarten addition to three separate public schools, being Andrew Hunter Public School, Assikinack Public School and Cundles Heights Public School.

2. **Description of Constrution**

   he three existing public schools are non-combustible buildings, one storey in building height, unsprinklered and do not contain a standpipe and hose system. Documentation provided by the Applicant indicated the following "building areas":

   Andrew Hunter
   Existing Building 37,339.6 ft²
   New Addition 3,938.7 ft²
   Total 41,278.3 ft²
   New Addition as Percentage of Old: 10.5%
   Assikinack
   Existing Building 25,960.7 ft²

Existing Attached	Portables	3,943.4 ft²
		29,904.1 ft²
New Addition		2,907.3 ft²
Total		32,811.4 ft²

New Addition as Percentage of Old: 9.7%

Cundles Heights

Existing Building	38,338.8 ft²
New Addition	2,505.7 ft²
Total	40,844.5 ft²

New Addition as Percentage of Old: 6.5%

3. **Dispute**

The dispute between the Applicant and Respondent concerns the technical interpretation of Article 1.1.3.2. for the definition of "building area" and sufficiency of compliance with the technical requirements of Clause 3.2.9.1.(1)(b) of the Building Code. At issue is the requirement to provide a standpipe and hose system for the proposed Junior Kindergarten additions to three separate Public Schools. Table 3.2.9.A. which forms part of Sentence 3.2.9.1.(1) of the Building Code requires a standpipe and hose system for one storey assembly "A" occupancies over 2500 m² (26,900 ft²) in "building area".

4. **Provision of the Building Code**

Article 1.1.3.2. Definitions of Words and Phrases "Building area" means the greatest horizontal area of a building above grade within the outside surface of exterior walls or within the outside surface of exterior walls and the centre line of firewalls.

Clause 3.2.9.1.(1)(b) Standpipe and Hose Systems

1. Except as provided in Article 3.2.9.2., a standpipe and hose system shall be installed in every building that

(b) is greater in building area than the area shown in Table 3.2.9.A. for the applicable building height shown in the Table where the building

i. is not sprinklered, and

ii. is not more than 14 m (45 m 11 in) high measured between grade and the ceiling of the top storey.

5. **Applicant's Position**

The Applicant submitted that the Respondent is requiring a standpipe and hose system to be provided only for the new Junior Kindergarten additions in each of the affected schools. This is based on the Respondent's interpretation of Subsection 3.2.9. of the Building Code that "building area" is the sum of the existing school and the addition.

The Applicant submitted that in accordance with Article 2.1.1.7. (existing buildings), the "building area" described in Subsection 3.2.9. should be the addition area, not the combined area.

The Applicant also submitted that even if "building area" is determined to be the combined area, the inclusion of a standpipe and hose system that serves only the addition does not improve the fire fighting or life safety standards of the building. The Applicant submitted that it would represent a possible danger to fire fighting and for fire fighters. A fire crew attending an alarm at the school may be lulled into a false sense of security seeing a siamese connection for a standpipe, and believing the entire school is protected.

6. **Chief Building Officials Position**

The Respondent submitted that the "building area" for each of the schools, once extended, exceeds the maximum "building area" limits shown in Table 3.2.9.A. for a Group A building. This requires a standpipe and hose system to be installed in the addition. The Respondent submitted that the options for construction are as follows:

a. construct a firewall;
b. sprinkler the addition; or,
c. install a standpipe and hose system in the addition.

The Respondent further submitted that increasing the "building area" without providing a standpipe and hose system may decrease the performance level of the existing building and is contrary to Article 11.3.1.1. of the Building Code. Also, Article 2.1.1.7. permits the Applicant to restrict the installation of the standpipe and hose system to the addition only, but does not allow the applicant to consider only the floor area of the addition in determining the application of Subsection 3.2.9. of the Building Code.

7. **Commission Ruling:**

   It is the decision of the Building Code Commission that not providing standpipe and hose systems in the Junior Kindergarten additions shows sufficiency of compliance with the Building Code.

8. **Reasons:**
   0. The additions are easily accessible by the fire department.
   1. Fire fighting would be conducted by the fire department using their own equipment.
   2. The additions are less than 15% of the gross floor area.
   3. Evacuation time is minimal since exiting directly to the exterior is provided from each of the additions.
   4. The buildings are of noncombustible construction.

Dated at Toronto, this 18th day, in the month of July, in the year 1995, for application number 1995-32.

For the Applicant

Mr. A. Howard Tishman
Keysite Equities
The Applicant

RULING

1. **The Applicant**

   Mr. A. Howard Tishman, Manager, Keysite Equities is the holder of a permit under the Building Code Act, 1992 to construct alterations and additions (including a greenhouse) to an existing mercantile occupancy, at White Rose, 43 Black Road, Sault Ste. Marie, Ontario.

2. **Description of Constrution**

   The existing 2174 m² single storey masonry building was built around 1975 with an unrated structural steel roof assembly which was protected by a sprinklering system conforming to Article 3.2.2.12. of the Building Code. The Applicant wishes to construct two new additions to the existing building and an unsprinklered 883 m² greenhouse structure with the gables flashed to the main building. The proposed new additions are required to be sprinklered in accordance with the NFPA-13 standard. This is based on the general Size and Occupancy requirements for fire safety regulated by Article 3.2.2.44. of the Building Code. The greenhouse is separated from the existing building by a 250 mm (10 inch) thick concrete block wall covered inside by steel studs with 1/2" gypsum board finish. Access is provided from the existing building into the greenhouse. The construction of the greenhouse provides complete ease of egress from the greenhouse in the event of a fire. The greenhouse has a tempered green canopy and except for three 12' sections, there are no permanent exterior nor interior walls.

3. **Dispute**

The dispute between the Applicant and Respondent concerns sufficiency of compliance with the technical requirements of Article 3.2.2.44. & Sentence 3.2.2.12.(1) of the Building Code. At issue is whether a sprinkler system is required in a greenhouse addition to an existing mercantile occupancy.

4. **Provision of the Building Code**

Article 3.2.2.44. Mercantile Buildings, up to 3 Storeys

1. A building classified as Group E shall conform to Sentence (2) provided the building
    a. is not more than 3 storeys in building height, and
    b. as a building area not more than the value in Table 3.2.2.M.
2. The building shall be of combustible or noncombustible construction used either singly or in combination, and
    a. floor assemblies shall be fire separations with a fire-resistance rating of not less than 45 min,
    b. mezzanines shall have, if of combustible construction, a fire-resistance rating of not less than 45 min,
    c. roof assemblies shall have a fire resistance rating of not less than 45 min, except that in buildings not more than 1 storey in building height, the fire-resistance rating is permitted to be waived provided the roof assembly is of noncombustible construction or is constructed as a fire-retardant treated wood roof system conforming to Article 3.1.14.1., and
        i. if unsprinklered, the building area is not more than 1 500 m? (16,100 ft?), and
        ii. if sprinklered, the building area is not more than 2 400 m? (25,800 ft?) if facing 1 street, 3 000 m? (32,300 ft?) if facing 2 streets, or 3 600 m? (38,800 ft?) if facing 3 streets,
    d. all loadbearing walls, columns and arches supporting an assembly required to have a fire- resistance rating shall have a fire-resistance rating of not less than 45 min or shall be of noncombustible construction, except that such members and assemblies supporting a fire separation shall have a fire-resistance rating not less than that required for supported assembly.

Sentence 3.2.2.12.(1) Sprinklers in Lieu of Roof Rating

3. The requirements in Articles 3.2.2.16. to 3.2.2.62. for roof assemblies to have a fire-resistance rating are permitted to be waived provided
    a. the building is sprinklered,
    b. the sprinkler system in Clause (a) is electrically supervised in conformance with Sentence 3.2.4.16.(5), and
    c. the operation of the sprinkler system in Clause (a) will cause a signal to be transmitted to the fire department in conformance with Sentence 3.2.4.7.(3).

5. **Applicant's Position**

The Applicant submitted that the requirement to sprinkler the greenhouse is excessive and should not be required in this instance for the following reasons:

1. The main building is of concrete block and steel construction and is fully sprinklered in compliance with the Building Code.
2. The greenhouse is accessory and subordinate to the Occupant's main use and the volume of people will be far less than in the main building.
3. The building/greenhouse arrangement was not contemplated when the subject Building Code regulation was being developed.
4. The purpose of the greenhouse is to provide an area of protective covering for plants and therefore the goods offered for sale to the public are non-combustible.
5. The greenhouse is separated from the building by a 10" concrete block wall covered inside by 3 ?" steel studs to which is applied ?" gypsum board.
6. The nature of the greenhouse construction allows complete ease of access/egress to the public in the event the need to exit the greenhouse should ever arise.
7. The greenhouse is composed of a tempered glass canopy. Except for three 12'- 0' sections, there are no permanent exterior nor interior walls.
8. The structure will not be used year round. Sprinkler or any other systems will be frozen over the winter months and will be affected by the elements.
9. There is such a degree of sufficiency of compliance with the Building Code that sprinklering the greenhouse should not be a requirement in this instance.

6. **Chief Building Officials Position**

The Respondent submitted that Article 3.2.2.44 and Sentence 3.2.2.12.(1) require mercantile buildings in excess of 16,100 ft² (1500 m²) to be sprinklered and that a supervised sprinkler system may be substituted in lieu of a fire rated roof assembly.

The Respondent also submitted that the existing 23,400 ft². (2174 m²) single storey, masonry building has an unrated structural steel roof assembly. It is undergoing alterations and the construction of two additions totalling 4,300 ft². (404 m²). Both additions and the existing building will be protected by a supervised sprinkler system. An unsprinklered 9,500 ft². (883 m²) greenhouse structure is being placed immediately adjacent to the main building with the gables flashed to the main building.

The Respondent submitted that the dispute arises out of the interpretation that the greenhouse is an extension of the main building and therefore must be sprinklered due to the total building area and the waiving of fire protection of the roof assembly as set out in Article 3.2.2.44. and Sentence 3.2.2.12.(1) respectively.

7. **Commission Ruling:**

   In favour of the Applicant. It is the decision of the Building Code Commission that the greenhouse structure shows sufficiency of compliance to the Building Code provided it is used only for the display and sale of horticultural products.

8. **Reasons:**
   1. The unheated structure is used seasonally and not in winter.
   2. The structure is non combustible in construction.
   3. The unenclosed greenhouse provides unlimited means of egress.
   4. The existing building is sprinklered and separated from the greenhouse by a 250 mm (10") masonry wall covered inside by steel studs with ?" gypsum board finish.

RULING

1. **The Applicant**

   Mr. Bryce Eldridge, Superintendent of Plant & Planning, York Region Roman Catholic Separate School Board, Aurora is an applicant for a permit under the Building Code Act, 1992 to construct a two storey multi-use building comprising two elementary schools, public library resource centre, child care facility and public pool.

2. **Description of Constrution**

   The public pool portion of the facility is classified as a Group A, Division 3, A-3 major occupancy and the remainder of the facility (i.e. two elementary schools, public library resource centre and child care facility) is classified as a Group A, Division 2, A-2 major occupancy. The leisure pool's building area consists of more than 10% of the entire ground floor building area.

   Article 3.2.2.27. (i.e. A-3, any height, any area) of the Building Code requires the public pool floor assembly to be constructed as a fire separation with a two hour fire resistance rating.

The remainder of the building has been designed to meet Article 3.2.2.22. (i.e. A-2, up to 5 storeys, any area) of the Building Code. The floor assemblies are required to be constructed as a fire separation with not less than a one hour fire resistance rating.

Article 3.1.3.3. of the Building Code states that where there are two major occupancies the requirements of the most restrictive (i.e. Article 3.2.2.27.) apply to the entire building. This would require the floor assemblies to be constructed as fire separations with a two hour fire resistance rating.

If a firewall with a two hour fire resistance rating was constructed between the public pool and the remainder of the building, a one hour fire resistance rating would be permitted for the floor assemblies in the entire two storey school.

3. **Dispute**

The dispute between the Applicant and Respondent concerns sufficiency of compliance with the technical requirements of Article 3.1.3.3. and Sentence 2.1.3.1.(1) of the Building Code. At issue is whether the provision of a sprinkler system and a 1 hour fire separation between the public pool and the remainder of the facility will provide sufficiency of compliance with the provision of a two hour firewall and thereby permit the remainder of the facility (i.e. all other portions than the leisure pool) to be developed under the classification of an A-2 occupancy.

4. **Provision of the Building Code**

Article 3.1.3.3. Construction Requirements

Except as provided in Articles 3.1.3.4. and 3.1.3.5., in any building containing more than 1 major occupancy, the requirements of Subsection 3.2.2. for the most restricted major occupancy contained shall apply to the whole building.

Sentence 2.1.3.1.(1) Building Divided by Firewalls

1. Where a firewall divides a building, each portion of the building so divided shall be considered as a separate building, except for the purpose of
    a. gross area determination in Section 2.3,
    b. a fire alarm and detection system in Sentence 3.2.4.2.(1) or Article 9.10.17.1., or
    c. a plumbing system interconnected through a firewall.

5. **Applicant's Position**

The Applicant submitted that in order to construct the floor assemblies as one hour fire separations a 2 hour firewall must be provided between the public pool (A-3 occupancy) and the remainder of the facility (A-2 occupancy).

The respondent submitted that the Chief Building Official was requested to permit a 1 hour fire separation between the public pool and the remainder of the facility and the inclusion of sprinkler system within the entire multi-use facility, (including the public pool) as an equivalent to the provision of a 2 hour firewall.

The Respondent submitted that the chlorination system for the public pool is a liquid type and not the traditional gaseous chlorine under pressure.

The Applicant submitted that providing a 1 hour fire separation between the two occupancies and sprinklering both sides of the fire separation is equivalent to providing a 2 hour firewall. Therefore, the remainder of the facility (i.e. all other portions than the public pool) should be permitted to be developed under the classification of an A-2 occupancy.

6. **Chief Building Officials Position**

The Respondent submitted that the public pool portion of the facility is an A-3 type occupancy and the remainder of the facility (two elementary schools, public library and a child care facility) is classified as an A-2 type occupancy. The public pool's building area constituted more than 10% of the entire ground floor building area.

The Respondent submitted that the proposal does not comply with the Building Code. Article 3.1.3.3. states that except as provided in Articles 3.1.3.4. and 3.1.3.5. in any building containing more than 1 major occupancy, the requirements of Subsection 3.2.2. for the most restricted major occupancy contained shall apply to the whole building.

The Respondent submitted that Articles 3.1.3.4. and 3.1.3.5. describe the requirements for major occupancies with relation to the entire building. Article 3.1.3.5. gives relief from the requirements of Subsection 3.2.2. provided the occupancy is less than 10% of the aggregate area of the building.

The Respondent also submitted that the area in question (i.e. containing the public pool) is more than 10% of the aggregate area and therefore must be considered a major occupancy and must be

taken into consideration with regards to Subsection 3.2.2., building size and construction relative to occupancy.

The Respondent does not have the authority to permit a deviation from the Building Code and the use of equivalents regulated by Section 2.7 is not applicable.

7. **Commission Ruling:**

In favour of the Applicant. It is the decision of the Building Code Commission that providing a fire separation with a 1 hour fire resistance rating with a sprinkler system provided on both sides of the separation between the A-2 and A-3 occupancies provides sufficiency of compliance with the Building Code.

8. **Reasons:**
    1. A liquid-type chlorination system to be used in the pool poses less of a fire hazard than the traditional pressurized chlorination system used in pools classified as A-3 occupancy.
    2. A sprinkler system has been provided on both sides of the 1 hour fire separation between the A-2 and A-3 occupancies.
    3. With respect to the pool area, the maximum allowable floor area percentage limit used to establish a major occupancy is exceeded by 5%.

Dated at Toronto, this 28th day, in the month of June, in the year 1995, for application number 1995-29.

BCC Ruling No. 95-32-452

BUILDING CODE COMMISSION DECISION ON B.C.C. #95-32-452

IN THE MATTER OF Subsection 24(1) of the *Building Code Act, 1992.*

AND IN THE MATTER OF Sentence 3.2.5.16.(2) of the Revised Regulation of Ontario 1990, Regulation 61, as amended by O.Regs. 400/91, 158/93, 160/93 and 355/94 (the "Building Code").

AND IN THE MATTER OF an application by Ms. R.J. Ross, Manager, Rockwood Mall for the resolution of a dispute with Mr. Agris Robeznieks, Chief Building Official, City of Mississauga, concerning whether the 60 m distance from the fire department connection to a hydrant provides sufficiency of compliance with Sentence 3.2.5.16.(2) of the Ontario Building Code, at 4141 Dixie Road, Phase II #1, Mississauga, Ontario.

RULING

1. **The Applicant**

   Ms. R.J. Ross, Manager, Rockwood Mall is the holder of a permit under the Building Code Act, 1992 to renovate an existing tenant space at the Rockwood Mall, 4141 Dixie Road, Phase II, Mississauga, Ontario.

2. **Description of Constrution**

   The Rockwood Mall has been is existence for approximately 20 years old. A change in occupancy to a tenant space resulted in an alteration of the existing sprinkler system.

   An existing fire department connection for the sprinkler system is situated on the north face of the building approximately 60 m from the existing fire hydrant near the north east corner of the building.

3. **Dispute**

The dispute between the Applicant and Respondent concerns sufficiency of compliance with the technical requirements of Sentence 3.2.5.16.(2) of the Building Code. At issue is whether the 60 m distance from the fire department connection to a hydrant provides sufficiency of compliance with the Building Code.

4. **Provision of the Building Code**

Sentence 3.2.5.16.(2) Fire Department Connections

2. Fire department connections for sprinkler systems shall be located so that the distance from a fire department connection to a hydrant is not more than 45 m (147 ft 8 in) and is unobstructed.

5. **Applicant's Position**

In 1994, a new tenant, "CLUB BIZ", (video equipment store) moved into the building. During the process of Building Permit Application for new tenant's improvement, there were revisions done to the existing sprinkler system. The building department requested the Applicant confirm the location of the hydrant which apparently does not comply with the Building Code.

The Applicant submitted that there was no alteration or expansion of the existing siamese connection.

The Applicant submitted that the present situation is safe, and that the 60 m distance between the fire hydrant and sprinkler siamese connection will not cause any undue hardship for the local fire department.

6. **Chief Building Officials Position**

The Respondent stated that the building was previously occupied by a retail lumber supply.

The Respondent submitted that the inadequacy of the existing sprinkler system required the system to be upgraded and split into two systems. The sprinkler density needed to be increased to cover the new use. The Respondent reported that the siamese connection was reworked to feed a header with 2 new alarm check valves. The only part of the sprinkler system that was not changed was the physical location of the siamese connection on the exterior of the building.

The Respondent submitted that the new sprinkler system must conform to NFPA-13 and the Building Code requirements. This requires the fire department connection to be within 45 m of a fire hydrant.

The Respondent stated that the existing fire hydrant is 60 m from the siamese connection. This is an increase of 33% over the maximum allowable 45 m required by the Building Code.

7. **Commission Ruling:**

   In favour of the Applicant. It is the decision of the Building Code Commission that the existing 60 m distance between the fire department connection and the fire hydrant provides sufficiency of compliance with the Building Code.

8. **Reasons:**
   2. The existing sprinkler system was voluntarily upgraded by the building owner within the subject tenant premises.
   3. No changes were made to the existing siamese connection or fire hydrant.
   4. There was no change in occupancy classification and no increase in occupant load.
   5. The existing fire safety performance of the building has been improved by the modifications.

Dated at Toronto, this 28th day, in the month of June, in the year 1995, for application number 1995-25.

For the Applicant

RULING

1. **The Applicant**

   Mr. Mander Gardiner, Plant Manager, Leeds & Grenville County Board of Education is the holder of a permit under the Building Code Act, 1992 to construct a new four classroom addition to an existing elementary school without providing a sprinkler system.

2. **Description of Constrution**

   The subject one storey building is an addition of four classrooms (450 m^2) to the existing (3400 m^2) South Branch Elementary School located at Part Lot 26, Concession 3, Oxford-on-Rideau Township, Town of Kemptville. The proposed new addition is required to be fully sprinklered in accordance with NFPA-13, including the newly added attic space. The proposed addition does not change the fire safety requirements determined for the original building in accordance with Subsection 3.2.2. of the Building Code.

   In May of 1992, the Leeds Grenville County Board of Education constructed a 3,400 m^2 elementary school. The school was designed to be fully sprinklered and included a horizontal 3/4 hour fire separation at the ceiling level throughout the school. The attic space was compartmentized and not sprinklered. This matter was considered by the Building Code Commission on August 20th, 1992 and subject to specific conditions was deemed to provide sufficiency of compliance with the Building Code.

3. **Dispute**

The dispute between the Applicant and Respondent concerns sufficiency of compliance with the technical requirements of Article 3.2.5.13. of the Building Code. At issue is whether not providing sprinkler protection in the attic space of a new four classroom addition to an existing elementary school provides sufficiency of compliance with the Building Code, at Abbott Road, Kemptville, Ontario.

4. **Provision of the Building Code**

Article 3.2.5.13. Automatic Sprinkler Systems

1. Except as provided in Sentences (2) and (3), where a sprinkler system is required, it shall be designed, constructed, installed and tested in conformance with NFPA 13, "Installation of Sprinkler Systems".
2. Where a building contains fewer than 9 sprinklers, the water supply for such sprinklers is permitted to be supplied from the domestic water system for the building provided the required flow and pressure for the sprinklers can be met by the domestic system.
3. Where a water supply serves both a sprinkler system and a system serving other equipment, control valves shall be provided so that either system can be shut off independently.
4. Open grid and translucent ceilings located below sprinkler systems shall be installed in conformance with NFPA 13, "Installation of Sprinkler Systems", paragraphs 4-4.14 and 4-4.15.
5. Where a sprinkler system has one or more electrically supervised control valves in order to meet the requirements of this Article, each valve shall be equipped with an electrically supervised switch for transmitting a signal for individual annunciation in the event of movement of the valve handle and the same annunciator panel may be utilized for supervision of valves in both the sprinkler and the standpipe systems.

5. **Applicant's Position**

The Applicant submitted that the Building Code Commission has ruled that the construction methods used in the existing elementary school provide sufficiency of compliance with respect to the requirement to sprinkler the attic spaces.

The Board of Education is constructing a four classroom addition to the school. The addition represents 11% of total area. The Applicant stated that he is seeking an extension of the previous Building Code Commission decision.

The addition does not affect the size, occupancy nor the fire safety requirements determined under Section 3.2 of the Building Code respecting this building.

6. **Chief Building Officials Position**

The Respondent submitted that Article 3.2.5.13. requires the sprinkler system to be installed in conformance with NFPA-13. Article 4.4.4.1. of NFPA-13 requires concealed spaces such as attics to be sprinklered.

The Respondent also submitted that the previous Building Code Commission ruling does not apply to the new addition.

The respondent does not have the authority to permit a condition that deviates from the Building Code and the use of equivalents regulated by Section 2.7 is not applicable.

7. **Commission Ruling:**

In favour of the Applicant. It is the decision of the Building Code Commission that the school addition shows sufficiency of compliance with the Building Code provided;

1. The attic for the addition is unheated and contains no mechanical or electrical services;
2. A continuous fire separation is provided with a minimum 45 minute fire resistance rating separating the building from the attic space;
3. The building's fire alarm system extends into the attic of the building addition;
4. The building's sprinkler system serves the floor area and extends into mechanical spaces;
5. A fire separation with a two hour fire resistance rating is provided between the attic of the addition and the attic of the existing building; and,
6. All aspects of the Building Code Commission decision #92-10-344 apply to the building addition.

8. **Reasons:**
    1. The floor area of the entire building is fully sprinklered and is less than 4800 m².
    2. Adequate exiting and travel distances are provided.
    3. The addition does not compromise existing life safety or property protection.

Dated at Toronto, this 20th day, in the month of June, in the year 1995, for application number 1995-27.

For the Applicant

RULING

1. **The Applicant**

   Mr. Bruce Mason, President, Lincoln Mechanical Contractors Ltd. is the holder of a permit under the Building Code Act, 1992 to install plumbing in an eleven storey fully sprinklered office building that includes a 150 mm (6 inch) galvanized steel pipe to convey potable water to the building at 301 St. Paul Street (160 King Street), St. Catharines, Ontario.

2. **Description of Constrution**

   The subject building is an eleven storey fully sprinklered high- rise office building. A portion of the sprinklered ground floor consists of office areas, loading docks and truck maneuvering bays. The building also includes a city and inter-city bus terminal comprised of a donut shop, waiting area, ticket office and washrooms located between two bus lanes and a service lane.

   Plumbing Permit Number P94-0625 was issued on December 2, 1994, to install plumbing in the building.

   A 150 mm (6 inch) galvanized steel pipe is installed in the potable water main starting from the building entry point to the suction side of the domestic cold water booster pumps.

   Copper piping is used from the domestic cold water booster pump discharge to the building water distribution system. The 150 mm (6 inch) galvanized pipe with Victaulic couplings

(between the two point described above) is installed exposed with the building and it is accessible.

3. **Dispute**

The dispute between the Applicant and Respondent concerns the technical interpretation of Article 1.1.3.2. for the definition of Water Distribution System, and Sentence 7.2.6.7.(3) of the Building Code. At issue is whether a 150 mm (6 inch) galvanized steel pipe to convey potable water is part of the water distribution system and subject to the Building Code.

4. **Provision of the Building Code**

Article 1.1.3.2. Definition of Words and Phrases

Water Distribution System means an assembly of pipes, fittings, valves and appurtenances that conveys water from the water service pipe or private water supply system to water supply outlets, fixtures, plumbing appliances and devices.

Sentence 7.2.6.7.(3) Steel Pipe

3. Galvanized steel pipe shall not be used in a water distribution system except
    a. in buildings of industrial occupancy, or
    b. for the repair of existing galvanized steel piping systems.

5. **Applicant's Position**

The Applicant submitted that the pipe in question is not a water distribution system in that it is situated prior to the meter and pumps and there is no branch piping running from it. Hence it does not come under Article 7.2.6.7. and the galvanized material should be acceptable.

The Applicant submitted that the pipe in question is completely accessible and therefore the intent of the provision is not contravened.

The Applicant referred to the Building Code which states that galvanized steel piping shall not be used in a water distribution system. The Applicant contends that this is not a water distribution system. There are no branch tees installed throughout the galvanized piping line. All branch tees for water distribution are after the discharge of the pump, which is copper piping.

The Applicant submitted that Niagara Mechanical Contractors would be willing to provide a reasonable extended warranty for the galvanized piping which is currently installed.

The Applicant also stated that other municipalities have accepted this on the basis of the equivalent provisions in Section 2.7 of the Building Code.

6. **Chief Building Officials Position**

The Respondent submitted that the applicant has installed a 150 mm (6 inch) galvanized steel pipe to convey potable water from the outside wall of the building to the suction side of the domestic water booster pump. The length of this pipe is approximately 125 feet.

The Respondent submitted that Sentence 7.2.6.7.(3) of the Building Code states that:

"Galvanized steel pipe shall not be used in a water distribution system except

c. in buildings of industrial occupancy or,
d. for the repair of existing galvanized steel piping systems".

The Respondent stated that the applicant does not wish to remove the galvanized steel pipe and replace it with pipe of an acceptable material and he was issued an inspection report on March 20, 1995, advising him of this matter. The Respondent submitted that Sentence 7.2.6.7.(1) of the Building Code states that welded and seamless steel pipe shall not be used in a plumbing system, except as follows:

"Galvanized steel pipe may be used in a drainage system or a venting system above ground inside a building". (Sentence 7.2.6.7.(2))

AND:

"Galvanized steel pipe shall not be used in a water distribution system except:

e. in buildings of industrial occupancy, or
f. for the repair of existing galvanized steel piping systems". (Sentence 7.2.6.7.(3))

The Respondent submitted that the installed galvanized steel pipe has been designed to carry potable water from the outside wall of the building to the suction side of the domestic water

booster pump. This pipe would be considered plumbing since it is part of a water system which by definition is considered plumbing, which means,

"a drainage system, a venting system and a water system or parts thereof".

The Respondent submitted that the pipe is part of a water system and not part of a drainage system or venting system. A drainage system is a system of pipes used to convey sewage and clear water waste to a main sewer. A venting system is a system of pipes that connects a drainage system to open air for circulation. Since this galvanized steel pipe is neither a drainage system nor a venting system the exception to permit the use of galvanized steel pipe does not apply.

The Respondent submitted that the galvanized steel pipe is designed to transport potable water from the outside wall of the building, that is the water service pipe, to the suction side of the domestic water booster pump, a plumbing appliance. By definition, this would be considered part of the water distribution system since water distribution system means,

"an assembly of pipes, fittings, valves and appurtenances that convey water from the water service pipe or private water supply system to water supply outlets, fixtures, plumbing appliances and devices".

This pipe conveys potable water from the water service pipe which means,

"a pipe on the (private) property that conveys potable water from a waterworks or private water source to the inside of the building",

and to a plumbing appliance, that is the booster pump. Therefore, the pipe would be considered part of the water distribution system.

The Respondent reported that the major occupancy of this building, as classified under the Building Code, is Business and Personal Service (Group D) and not industrial (Group F). Therefore, the exception to permit the use of galvanized steel pipe in an industrial occupancy would not apply.

This building is a new building and there is no existing piping. Therefore, the exception to permit the use of galvanized steel pipe to repair existing galvanized steel piping would also not apply.

In conclusion, the Respondent stated that this galvanized steel pipe:

. is considered plumbing, since it is part of a water system,
i. is not part of a drainage system,
ii. is not part of a venting system,
iii. is part of a water distribution system,
iv. is not located in an industrial occupancy, and
v. is not being used to repair existing galvanized steel pipe.

Therefore, Sentence 7.2.6.7.(1) of the Plumbing Regulations in Part 7 of the Building Code does not permit galvanized steel pipe to be used as part of the water distribution system. The galvanized steel pipe must be removed and replaced with an acceptable material.

2. **Commission Ruling:**

In favour of the Applicant. It is the decision of the Building Code Commission that the water service pipe conforms to the requirements of the Building Code.

3. **Reasons:**
    0. The pipe is installed before the water meter and is considered a water service pipe. It contains no branches and is not considered part of the water distribution system.
    1. The water service pipe is 6" in diameter with a sufficiently slow flow not making it susceptible to restricted flow from corrosion.
    2. The water service pipe is accessible across its entire length.
    3. Evidence presented suggests that large diameter galvanized pipe has been used in other municipalities on the basis of past performance.

Dated at Toronto, this 20th day, in the month of June, in the year 1995, for application number 1995-28.

BCC Ruling No. 95-29-449

BUILDING CODE COMMISSION DECISION ON B.C.C. #95-29-449

IN THE MATTER OF Subsection 24(1) of the *Building Code Act, 1992.*

AND IN THE MATTER OF Article 6.2.2.6. of the Revised Regulation of Ontario 1990, Regulation 61, as amended by O.Regs. 400/91, 158/93, 160/93 and 355/94 (the "Building Code").

AND IN THE MATTER OF an application by Mr. Lew King, Co-owner, Alternatives Natural Food Market for the resolution of a dispute with Mr. Frank Asta, Chief Building Official, Town of Oakville, concerning whether the exhaust system for cooking equipment used for the purpose of customer and staff demonstrations at Kerr Centre provides sufficiency of compliance with Article 6.2.2.6. of the Building Code, at 579 Kerr Street, Oakville, Ontario.

APPEARANCES

Mr. Lew King, Co-owner
Alternatives Natural Food Market
The Applicant

Mr. John Peters
Chief Fire Prevention Officer
Town of Oakville
For the Respondent

RULING

1. **The Applicant**

   Mr. Lew King, Co-owner, Alternatives Natural Food Market received an order to comply under the Building Code Act, 1992 to provide an exhaust system for the cooking equipment used for customer and staff demonstrations in conformance with NFPA-96 at the Kerr Centre, 579 Kerr Street, Oakville, Ontario.

2. **Description of Constrution**

   The subject building includes an area where household cooking equipment has been installed for the purpose of conducting cooking demonstrations. Food is not prepared for any other purpose.

3. **Dispute**

   The dispute between the Applicant and Respondent concerns sufficiency of compliance with the technical requirements of Article 6.2.2.6. of the Building Code. At issue is whether the requirements of NFPA-96, "Installation of Equipment for the Removal of Smoke and Grease-Laden Vapours from Commercial Cooking Equipment" need be applied to the household cooking equipment being used for the purpose of customer and staff demonstrations.

4. **Provision of the Building Code**

   Article 6.2.2.6. Commercial Cooking Equipment

Systems for the ventilation of restaurant and other commercial cooking equipment shall be designed, constructed and installed to conform to NFPA-96, "Installation of Equipment for the Removal of Smoke and Grease-Laden Vapours from Commercial Cooking Equipment", except as required by Sentences 3.5.3.1.(1) and Article 3.5.4.2.

5. **Applicant's Position**

The Applicant submitted that household cooking equipment has been installed for the purpose of conducting cooking demonstrations. All demonstrations are done with recipes that only serve 4 - 6 people (i.e. mass quantities are not served). The recipes are very low in fat and are meat free (e.g. no hamburgers, fries, etc.). Therefore, no smoke is produced and vapours are not grease laden.

The applicant stated that the demonstration premises are supervised, locked when not in use and provided with fire extinguishers. The cooking equipment is also provided with a down draft system that exhausts outdoors.

The applicant submitted that there are many examples of similar demonstration set-ups used throughout the Province for trade shows, exhibits and promotions.

6. **Chief Building Officials Position**

The Respondent submitted that the cooking equipment is used to prepare meals. Therefore, the stove requires a commercial hood and suppression system in conformance to NFPA-96. The Respondent stated that the municipality is concerned about the safety of the people watching the cooking demonstration.

The Respondent also stated that daycare facilities in the Town of Oakville that have stove top cooking equipment are required to comply with NFPA-80.

The Respondent does not have the authority to permit a condition that deviates from the Building Code and the use of equivalents regulated by Section 2.7 is not applicable.

7. **Commission Ruling:**

In favour of the Applicant. It is the decision of the Building Code Commission that the residential stove and down-draft system shows sufficiency of compliance with the Building Code provided that:

1. No more than 20 people are present within the demonstration area at any one time.
2. Use of the stove is restricted to occasional cooking demonstration only attended by trained personnel at all times.
3. Demonstrations are carried out by persons trained in the use of the cooking equipment and fire extinguishers.
4. Fire extinguishers must be located where clearly visible.
5. The gas line to the stove must be locked off when the stove is not in use for cooking demonstrations.
6. No other stoves or cooking ovens are permitted within the demonstration area.

8. **Reasons:**
    1. The stove is a residential - type stove.
    2. No smoke or grease-laden vapours will be produced by the preparation of meals.
    3. Cooking is for demonstrations only and is not continuous as in most commercial applications.
    4. Only trained personnel will operate the equipment.

Dated at Toronto, this 20th day, in the month of June, in the year 1995, for application number 1995-26.

For the Respondent

RULING

1. **The Applicant**

   Mr. Normand D. Tremblay, Loeb St. Laurent is the holder of a permit under the Building Code Act, 1992 to alter the front vestibule and one exit at the front of Loeb St. Laurent, 1021 St. Laurent Blvd., Gloucester, Ontario.

2. **Description of Constrution**

   The subject building is a one storey grocery store (i.e. Mercantile, Group E major occupancy). The building area is approximately 2393 m² (25759 ft²). The building is sprinklered, but does not have a fire alarm system that complies with Subsection 3.2.4. of the Building Code.

   Electromagnetic locking devices have been installed on three exit doors of the store. The Applicant would like to install a fire alarm that only satisfies the specific requirements for electromagnetic locking devices. The applicant does not want to install a complete fire alarm system in accordance with the installation and testing requirements in Article 3.2.4.5. of the Building Code.

3. **Dispute**

The dispute between the Applicant and Respondent concerns sufficiency of compliance with the technical requirements of Sentences 3.4.6.15.(3) and 3.4.6.15.(4) of the Building Code. At issue is whether a partial fire alarm system that only satisfies the specific requirements for three electromagnetic locking devices installed on exit doors at Loeb St. Laurent shows sufficiency of compliance with the Building Code.

4. **Provision of the Building Code**

Sentences 3.4.6.15.(3) & 3.4.6.15.(4) Door Release Hardware

3. Locking, latching and other fastening devices on any required exit door shall be each that the door can be readily opened from the inside without requiring keys, special devices or specialized knowledge of the door opening mechanism, except that this requirement does not apply to locking, latching and other fastening devices described in Sentence (4) or to doors designed to be remotely released in conformance with Article 3.3.1.12. serving a contained use are or an impeded egress zone.
4. An electromagnetic locking device that does not incorporate latches, pins or other similar devices to keep the door in the closed position is permitted to be installed on an exit door, other than an exit door serving an elementary or secondary school or leading directly from a Group F, division 1 occupancy
    a. if the building is equipped with a fire alarm system conforming to Subsection 3.2.4.,
    b. if the locking device is installed as an ancillary device to the fire alarm system and releases immediately
        i. upon activation of the fire alarm signal,
            - where the exit door serves a hotel, upon activation of the alert signal where a two stage fire alarm system is installed or upon activation of the alarm signal where a single stage fire alarm system is installed,
        ii. in the event of a power failure or ground fault, and
        iii. upon actuation of a manually-operated switch accessible only to authorized personnel,
    c. if a manual pull station for the fire alarm system is located on the wall not more than 600 mm (23 5/8 in) from the door,
    d. if, upon its release, the locking device must be reactivated manually by the actuation of the switch referred to in Subclause (b) (iii),

e. if a legible sign having the words EMERGENCY EXIT UNLOCKED BY FIRE ALARM is permanently mounted on the door, and
f. if the lettering on the sign required in Clause (e) is at least 25 mm (1 in) high with a 5 mm (3/16 in) stroke.

5. **Applicant's Position**

The Applicant submitted he was requested to either remove the electromagnetic locking devices on the exit doors or modify them to conform with the provisions of Article 3.4.6.15. of the Building Code. This article states that such devices are to be installed as an ancillary device to a fire alarm system.

The Applicant submitted that the store was built in 1968 and does not have a fire alarm system that complies with the Building Code. The Applicant is prepared to install a fire alarm system that will satisfy the specific requirements for electromagnetic locking devices. The Applicant submitted that the Respondent is requiring the fire alarm system to be installed and testing in conformance with Article 3.2.4.5. (i.e. CAN/ULC-S524 and S537) of the Building Code. This would mean a complete fire alarm system throughout the entire store. The applicant requested that he be exempted from installing a full fire alarm system due to the following reasons:

3. The cost of such an elaborate system is at least four times more expensive than what is actually needed for the electromagnetic locking devices, and he cannot afford it.
4. The provision of a partial fire alarm system that only satisfies the specific requirements for three electromagnetic locking devices insalled on the exit doors shows sufficiency of compliance with the Building Code.
5. The building has a sprinkler system plus a comprehensive fire detection system monitored 24 hours day by a security company.

6. **Chief Building Officials Position**

The Respondent submitted that a permit was obtained to alter the front vestibule and one exit at the front of a one storey (Group E) grocery store. The store is sprinklered, but does not have a fire alarm system. An Electromagnetic Locking Device (EMLD) was installed on the front exit and on two rear exits that are not part of the building permit. The EMLD's were not shown on the original documents submitted with the building permit application.

The Respondent submitted that the building is not provided with a fire alarm system conforming to Subsection 3.2.4. as required in Clause 3.4.6.15.(4)(a) of the Building Code. Also the

release/reset features required by Clause 3.4.6.15.(4)(b) of the Building Code are not provided. Therefore the EMLDs are not permitted to be installed in the building.

The Respondent does not have the authority to permit a condition that deviates from the Building Code and the use of equivalents regulated by Section 2.7 is not applicable.

7. **Commission Ruling:**

In favour of the Respondent. It is the decision of the Building Code Commission that the electromagnetic locking devices on three (3) required exit doors do not demonstrate sufficiency of compliance with the Building Code.

8. **Reasons:**

- Sentence 3.4.6.15.(4) permits electromagnetic locking devices on required exit doors only in buildings equipped with a fire alarm system conforming to Subsection 3.2.4. of the Building Code.

- Insufficient evidence was provided that the existing security system can function as an acceptable fire alarm system.

Dated at Toronto, this 30th day, in the month of May, in the year 1995, for application number 1995-23.

APPEARANCES

Mr. Arnold Kimmel, Owner
Kareeka Holdings Ltd.
Cornwall, Ontario
For the Applicant

RULING

1. **The Applicant**

   Mr. Arnold Kimmel, Owner, Kareeka Holdings Ltd. is the holder of a permit under the Building Code Act, 1992 to construct a new Speedy Muffler King building, at 708 Fourteenth Street West, Cornwall, Ontario.

2. **Description of Constrution**

   The proposed building is a Speedy Muffler King shop (Group F, Division 2), the north face of which is set back 8.37 m from the property line. The allowable percentage of unprotected openings in the north exposing building face is 22% whereas the actual percentage is calculated to be 29%. The exposing building face is constructed of masonry and allegedly complies with the fire-resistance rating requirements for spatial separation.

3. **Dispute**

   The dispute between the Applicant and Respondent concerns the sufficiency of compliance with the technical requirements of Subsection 3.2.3. and Article 3.2.3.1. of the Building Code. At issue is whether the area of unprotected openings for the north exposing building face of the new Speedy Muffler King building shows sufficiency of compliance with the Building Code.

4. **Provision of the Building Code**

   Subsection 3.2.3. Spatial Separation and Exposure Protection of Buildings

   Article 3.2.3.1. Limiting Distance and Area of Unprotected Openings

1. Except as provided in Articles 3.2.3.9. to 3.2.3.11, the area of unprotected openings shall not be more than that set forth in Tables 3.2.3.A. or 3.2.3.B. for the limiting distance applicable to the exposing building face under consideration.
2. The area of the unprotected openings in an exposing building face shall be the aggregate area of unprotected openings expressed as a percentage of the area of the exposing building face in Tables 3.2.3.A. and 3.2.3.B.(Sentence 3.2.3.2.(1).)
3. For the purposes of determining the type of construction and cladding and the fire-resistance rating of an exterior wall, the exposing building face shall be taken as the projection of the exterior wall onto a vertical plane located so that no portion of the exterior wall of the building or of a fire compartment, if the fire compartment complies with the requirements of Sentence 3.2.3.2.(1), is between the vertical plane and the line to which the limiting distance is measured and, for these purposes, the area of unprotected openings shall be determined from Table 3.2.3.A. or Table 3.2.3.B.
4. For the purposes of determining the actual percentage of unprotected openings permitted in an exterior wall, the location of the exposing building face is permitted to be taken at a vertical plane located so that there are no unprotected openings between the vertical plane and the line to which the limiting distance is measured.
5. Where fire fighting facilities cannot reach the building within 10 min of the alarm being received, the limiting distance shall be doubled.

5. **Applicant's Position**

The Applicant submitted that the subject building is a muffler repair shop. The large service bay doors result in the percentage of openings in the north exposing building face that is relatively high. The Applicant submitted that the exposing face is constructed of masonry and complies with requirements for fire resistance rating, but the maximum permitted area of unprotected openings is 22% as opposed to an actual area of 29%. The Applicant requested relief from the Building Code with respect to the additional 7% area of unprotected openings. The building is set back 8.37 m from the property line and approximately 50 m to an adjacent hotel.

The Applicant submitted that if his application is rejected, a fire-rated shutter will be provided to the exterior of the building to close off one of the standard doors. This will in effect reduce the area of unprotected openings to less than 22% of the exposing building face.

6. **Chief Building Officials Position**

The Respondent submitted that the building drawings indicated that the north exposing building face contains unprotected openings in excess of 22%. This is the maximum allowed in Article 3.2.3.1. of the Building Code. Therefore, the proposed 29% of unprotected openings in north exposing building face does not comply with the Building Code.

The Respondent does not have the authority to permit a condition that deviates from the Building Code and the use of equivalents regulated by Section 2.7 is not applicable.

7. **Commission Ruling:**

In favour of the Respondent. It is the decision of the Building Code Commission that the unprotected openings in the north building face do not comply with the requirements of Subsection 3.2.3 and Article 3.2.3.1. of the Building Code.

8. **Reasons:**

Aggregate area of unprotected openings in the north face (29%) exceeds the percentage allowed by Table 3.2.3.B. of the Building Code.

Dated at Toronto, this 30th day, in the month of May, in the year 1995, for application number 1995-17.

For the Applicant

RULING

1. **The Applicant**

   Mr. Greg Graham, Palladium Corporation is the holder of a permit under the Building Code Act, 1992 to construct a new National Hockey League (NHL) hockey arena for the Ottawa Senators at 1000 Palladium Drive, Kanata, Ontario.

2. **Description of Constrution**

   The Ottawa Palladium is a new NHL hockey arena for the Ottawa Senators. The facility will seat approximately 19,000 people and will have three tiers of seating.

   The facility includes an upper tier of fixed seats where the rise between rows is approximately 600 mm. The Applicant does not wish to provide guards between these rows of fixed seats. Clause 3.3.2.8.(1)(c) of the Building Code requires a 660 mm high guard to be provided where the seating is arranged in successive tiers and the height between platforms is more than 450 mm.

   The seating configuration in the Palladium has been designed in accordance with NFPA 101 "Life Safety Code". This includes the use of sophisticated smoke management systems to enhance the level of safety and maintain smoke protected routes during evacuation of the building. The NFPA 101 requires handrails in the aisles of this seating section that are not required by the Building Code.

3. **Dispute**

The dispute between the Applicant and Respondent concerns the sufficiency of compliance with the technical requirements of Clause 3.3.2.8.(1)(c) of the Building Code. At issue is whether the upper tier seating design that does not provide 660 mm high guards between rows of fixed seats shows sufficiency of compliance with the Building Code.

4. **Provision of the Building Code**

Clause 3.3.2.8.(1)(c) Guards

1. Except as required in Sentence (2) to (4) for bleacher seats, guards shall be installed in outdoor and indoor places of assembly with fixed seating so that:

(c) where the seating is arranged in successive tiers and the height of rise between platforms
is more than 450 mm, the height of guards is not less than 660 mm along the entire row of
seats at the edge of the platform.

5. **Applicant's Position**

The Applicant submitted that Clause 3.3.2.8.(1)(c) of the Building Code is not applicable to rows of fixed seats. It was suggested that this requirement was originally intended for a platform of loose seats. Such a platform created isolated seating areas which in more recent designs have been replaced by private boxes.

The Applicant submitted that even if Clause 3.3.2.8.(1)(c) of the Building Code is considered applicable to fixed rows of seats, the proposed design provides an equivalent level of performance:

1. The seating configuration has been designed in accordance with NFPA 101 "Life Safety Code" that does not require guards in fixed seating rows.
2. Typically trip and fall related injuries occur on stairs. Although handrails are not required by the Building Code in seating aisles and steps, handrails will be provided in aisles in this tier of seating.
3. Past experience supports the conclusion that tiers of fixed seats perform acceptably without guards located between rows.

6. **Chief Building Officials Position**

   The Respondent submitted that the proposed upper tier seating has successive seating risers of 597 mm that will not have guards in the rows nor will the seat back extend more than 600 mm above the floor of the row behind.

   The Respondent submitted that records and reports indicate that there does not appear to have been any accidents or injuries in similar seating tiers without guards. The proposed seating has been designed in accordance with NFPA 101 Life Safety Code.

   The Respondent does not have the authority to permit a condition that deviates form the Building Code and the use of equivalents regulated by Section 2.7 is not applicable.

7. **Commission Ruling:**

   In favour of the Applicant. It is the decision of the Building Code Commission that the upper seating design, that does not provide 660 mm high guards between rows of fixed seating, shows sufficiency of compliance with the Building Code.

8. **Reasons:**
   1. Seating has been designed to NFPA 101 "Life Safety Code" and includes such safety features as handrails in seating aisles, which exceeds the Building Code requirements.
   2. Evidence based on past studies supports the acceptability without guards located between rows.
   3. Evidence presented indicates that trip and fall related injuries usually occur on stairs rather than within seat rows.

Dated at Toronto, this 30th day, in the month of May, in the year 1995, for application number 1995-24.

RULING

1. **The Applicant**

   Mr. Jim Shier, Ontario Store Fixtures is the holder of a permit under the Building Code Act, 1992 to construct an interconnected second floor assembly in the Group D portion of an existing building used primarily for wood cutting and assembly operations at Ontario Store Fixtures, 650 Barmac Drive, North York, Ontario.

2. **Description of Constrution**

   The project is a 4,000 m² fully sprinklered, noncombustible building classified as a Group F, Division 2, major occupancy. The north portion of the building consists of a two storey, interconnected office space representing approximately 2,600 m² or 65% of the building area. The north portion of the building is a one storey structure used primarily for wood cutting and assembly operations, classified as a Group F, Division 2 occupancy. The Group D portion of the building is separated from the Group F, Division 2 portion by a 1 hour vertical fire separation rising tight to the underside of the metal deck roof.

   The Applicant constructed a non rated interconnected second floor assembly in the Group D portion of the building.

3. **Dispute**

The dispute between the Applicant and Respondent concerns the sufficiency of compliance with the technical requirements of Clause 3.2.2.52.(2)(a) of the Building Code. At issue is whether the provision of a 1 hour vertical fire separation between the Group F, Division 2 and Group D occupancies provides sufficiency of compliance with the requirement to provide a 45 minute fire resistance rating for the adjoining interconnected second floor of the Group D occupancy.

4. **Provision of the Building Code**

Clause 3.2.2.52.(2)(a): Industrial Buildings, Division 2, up to 4 Storeys

2. The building shall be of combustible or noncombustible construction used either singly or in combination, and

b. floor assemblies shall be fire separations with a fire-resistance rating of not less than 45 min,

2. **Applicant's Position**

The Applicant submitted that the North York Building Department is requiring the second floor assembly to have a 45 minute fire-resistance rating in conformance with Clause 3.2.2.52.(2)(a) for a Group F, Division 2 major occupancy, and Article 3.1.3.3. respecting construction requirements for the most restrictive major occupancy. The Applicant submitted that sufficiency of compliance with Clause 3.2.2.52.(2)(a) of the Building Code has been achieved, for the following reasons:

2. The vertical fire separation is equivalent in rating to the floor assembly rating if the floor was designed to Group F, Division 2 requirements.
3. Since the Group D portion of the building is separated from the Group F, Division 2 portion by a 1 hour rated vertical fire separation, a fire occurring in the Group F, Division 2 portion of the building will not immediately threaten the structural integrity of the non-rated second floor assembly in the Group D portion of the building.
4. In sprinklered Group D buildings up to three storeys in building height, facing a minimum of one street and having a building area of not more than 4,800 m², noncombustible floor assemblies may be used.

The Applicant summarized that the City of North York Building Department maintains the opinion that a 45 minute fire-resistance rating must be applied to the underside of the second

floor assembly in consideration of the construction requirements for the most restrictive major occupancy (i.e. Group F, Division 2).

It is the Applicant's opinion that the 1 hour vertical fire separation between the two adjoining occupancies provides a reasonable level of safety to the occupants within the Group D portion of the building from an ensuing fire in the Group F, Division 2 portion of the building, and therefore sufficiency of compliance is achieved with a non-rated floor assembly in the Group D portion.

2. **Chief Building Officials Position**

The Respondent submitted that the ground floor of the subject building is classified as Group D and Group F, Division 2 major occupancy. For construction requirements the building falls under Article 3.2.2.40 and 3.2.2.52. of the Building Code.

Sentence 3.1.3.1.(2) and Article 3.1.3.3. require the most restrictive major occupancy contained in a building to be applied to the whole building. The most restrictive of the two major occupancy is Group F, Division 2. Clause 3.2.2.52.(2)(a) requires the floor assembly to be constructed as a fire separation with a fire resistance rating of not less than 45 minutes.The Respondent does not have the authority to permit a condition that deviates from the Building Code and the use of equivalents regulated by Section 2.7 is not applicable.

3. **Commission Ruling:**

In favour of the Respondent. It is the decision of the Building Code Commission that not providing the 45 minute fire resistance rating on the second floor does not comply with the Building Code.

4. **Reasons:**
    2. The Medium Hazard Industrial Occupancy (F-2) requirements apply throughout the building since no fire wall is provided to treat the Business and Personal Service Occupancy (D) and F-2 occupancy as separate buildings.
    3. Sentence 3.1.3.1.(2) and Article 3.1.3.3. require the most restrictive major occupancy contained in a building to be applied to the whole building. The most restrictive of the two major occupancy is Group F, Division 2. Clause 3.2.2.52.(2)(a) requires the floor assembly to be constructed as a fire separation with a fire resistance rating of not less than 45 minutes.

Dated at Toronto, this 18th day, in the month of May, in the year 1995, for application number 1995-20.

APPEARANCES

Mr. Michael Gooch
Building Inspector
Town of Bracebridge
For the Respondent

RULING

1. **The Applicant**

   Ms. Joy McCormack, Muskoka Women's Advocacy Group is the holder of a permit under the Building Code Act, 1992 to construct a Part 9 building, classified as a Group C major occupancy to be used as a battered women's shelter, "Muskoka Interval House", 43 Mary Street, Bracebridge, Ontario.

2. **Description of Constrution**

   The subject building was designed and built as a single family dwelling (i.e. house). It is being used as a shelter for battered women. The building has 10 sleeping rooms with an occupant load of 20. In-house supervision is provided 24 hours a day.

3. **Dispute**

   The dispute between the Applicant and Respondent concerns the sufficiency of compliance with the technical requirements of Article 9.9.6.8. of the Building Code. At issue is whether the electromagnetic locking devices on two exterior doors sufficiently comply with the Building Code.

4. **Provision of the Building Code**

   Article 9.9.6.8.: Door Opening Mechanism

   Exit doors and doors to suites, including exterior doors to dwelling units, shall be openable from the inside without requiring keys, special devices or specialized knowledge of the door opening mechanism.

5. **Applicant's Position**

The Applicant submitted that the operating procedures for this shelter for battered women provides that only staff members may open from the interior, any of the five exterior doors. The doors in contention (i.e. the 'front door' and the 'basement door') are equipped with electrically operated unlocking devices activated by touch-keys, the fire alarm system, and a power failure.

The applicant submitted that two of the exterior doors, door D31 (i.e. the east exit door) and door D43 (i.e. the west exit door) are equipped with door release hardware conforming with Article 3.4.6.15. The Building Department has accepted this arrangement as an equivalent with respect to these two doors complying with Article 9.9.6.8. of the Building Code.

It is the Applicant's position that:

1. the east exit door and the west exit door are the required exits to the exterior,
2. the east exit door and the west exit door are the only required exits to the exterior,
3. the front door and the basement door are not required exits to the exterior,
4. the required exit doors comply with Article 9.9.6.8.
5. the front door and the basement door are not required to comply with Article 9.9.6.8., and
6. in addition to the above, the intent of the Building Code with respect to door release hardware on doors that are not required exits is found in Sentence 3.4.6.15.(3).

6. **Chief Building Officials Position**

The Respondent submitted that Article 9.9.6.8. requires that all exterior doors to dwelling units be openable without the use of keys, special devices or specialized knowledge. The latches that have been installed are electromagnetic, using pins or latches that can be opened with a touch key. They can be programmed or wired to not open on power failure or on the activation of the fire alarm. The Building Department has not been provided with the specifications for the latches. These latches do not comply with Article 9.9.6.8. or Sentence 3.4.6.15.(4).

The Respondent does not have the authority to permit a condition that deviates from the Building Code and the use of equivalents regulated by Section 2.7 is not applicable.

7. **Commission Ruling:**

In favour of the Applicant. It is the decision of the Building Code Commission that the subject exterior doors from the building provide sufficiency of compliance with the Building Code.

8. **Reasons:**

1. Two exits that comply with the Building Code have been provided from every floor area.
2. Twenty four hour supervision is provided by staff.
3. Emergency procedures on exiting the building are included in the fire safety plan.
4. All residents are oriented on fire emergency procedures.
5. The building has limited public access.

Dated at Toronto, this 18th day, in the month of May, in the year 1995, for application number 1995-22.
